VACCINE TREATMENT

LUDVIG HEKTOEN, M.D.
CHICAGO

My intention is to discuss briefly certain more or less recent developments in connection with vaccine treatment. For this purpose it is not now necessary to review in detail the various stages in the growth of knowledge on which the principles and practice of vaccination preventive as well as curative are based. The aim in either case has been to strengthen and to hasten the natural processes that result in protection against infection and in cure of infection.

Curative vaccine treatment which I shall discuss is a direct outgrowth of the increasingly successful prevention of various infectious diseases by means of artificial immunization, and may be said to represent a culmination of the efforts to combat infection with its own weapons, as it rests primarily on the assumption that under certain conditions the production of specific antibodies by the infected organism can be increased with curative results on injection of special preparations of the virus or the bacteria which caused the infection.

This conception is in full harmony with the accepted interpretation of the preventive action of many bacterial and other vaccines or antigens as due to the easily demonstrable formation of new and specific antibodies, which persist for a longer or shorter time, and to the greater readiness, which also is demonstrable in various ways, with which such formation is renewed when the antigen again enters the vaccinated body, as may occur in the form of the living germs. Except as tested in Pasteur's experiments on inoculation against rabies after the infection has been received, this explanation of the supposedly curative action of vaccines has not been put to the direct test in animal experiments, largely, it seems, because the animal infections with which we are acquainted are not regarded as suitable for that purpose since they do not appear to duplicate sufficiently the human conditions. Whether or not the practical results of vaccine treatment for curative purposes support the hypothesis as to the mode of action on which it is based is even now a debatable question. The conditions under which vaccine treatment is practiced have been allowed to change so much since its formal introduction by Wright in 1902, and have acquired in large degree such character, that there are no secure foundations for comprehensive interpretation and final judgment as to the practical value and significance of the results. A hurried review of events may serve to make this point clearer.

In the early days after Wright's discovery of the opsonins and his advocacy of specific vaccine treatment under the guidance of the opsonic index much attention was given to this index as a measure of specific resistance and in less degree as a means of diagnosis. Soon doubts arose as to the value of the index, the accuracy of the method was questioned, and emphasis was put on the limitations of the results as not being a measure of the final degree of immunity because applicable to one factor only, leaving unmeasured other factors equally important and not necessarily subject to parallel fluctuations of activity. The outcome was the abandonment of the index as an essential element in vaccine treatment, which in the meantime rapidly passed into general use and, at least in this country, soon became the object of an unrestrained and indiscriminate exploitation, to which the medical profession has offered but little resistance. In a short time various practices were introduced, which are not in harmony either with the conditions demanded by the primary hypothesis or with the teachings of bacteriology and immunology, and which before long reduced vaccine treatment as generally practiced from a carefully controlled, essentially scientific procedure to one of guesswork and routine.

The first departure from the course of safety and conservatism was the uncontrolled delegation of the making of vaccines to commercial concerns. According to the fundamental principles, every consideration but that of expediency demands that therapeutic vaccines shall be composed of bacteria as little different and as little removed as possible from the strains causing the infections against which the vaccines are to be used. It is evident that in preparing vaccines on a large scale this condition cannot be met because the changes in virulence and affinities which take place in bacteria under artificial cultivation cannot be avoided. Indeed, there is always danger that with time the specific element on which the desired antigenic effect depends may be lost altogether. There is the further difficulty that the antibodies evoked by one strain may not act on other strains of the same species. That this is not placing undue importance on some remote possibility of no real practical significance is shown conclusively by the regular occurrence of fixed varieties according to antigenetic properties in certain species of pathogenic bacteria as illustrated so well by the pneumococcus. So far as we now know, there are no all-inclusive strains of bacteria causing human infections which might be used to overcome this narrow specificness of immunizing action. In recognition of this drawback to wholesale vaccine making, the polyvalent vaccine was evolved and made to contain so many strains from different sources that every possibility would seem to have been covered But after all this is an unsatisfactory substitute for the fresh autogenous vaccine, which, it would seem, offers the best hope that the indications of each case at all times will be met in the most direct way The principle of using autogenous vaccine as the rule has the further great advantage that to secure it the definite etiology of the infection must be established — a true etiologic diagnosis must be made and there is an end to guesswork Undoubtedly the good results obtained by careful scientific physicians who use autogenous vaccines are due in no small degree to the careful study of the patient whereby is disclosed not only the nature of the outstanding infection but in many cases also hidden bacterial foci that often perhaps are the primary source of the evident localizations, and hence require removal before permanent cure can be established

It was the inability of most physicians to make or have made the bacteriologic studies necessary to obtain the etiologic diagnosis coupled with demand for vaccine treatment that paved the way for the commercial vaccine and also for the second, but less excusable and more harmful, departure from the proper course, namely, the acceptance by physicians of the short cut to vaccine treatment without careful diagnosis offered by the ready made mixed vaccines and by semisecret, unstandardizable mixtures of bacterial products—phylacogens Carried to its logical conclusion, the reasoning that led to these makeshifts would justify the same treatment of all infections, the only diagnosis required being infection As to semisecret cultural filtrates, no reason can be found to warrant their use as vaccines their antigenic values, if they have any, have not been determined, they are not uniform in composition and cannot be standardized, they are more or less toxic, the toxicity being affected by small but uncontrollable differences in the conditions under which bacterial growth takes place At the same time as commercial mixed vaccines contain no autogenous elements, there is the further evident objection that there exists no such constancy of bacterial association in mixed infections as would permit the use of ready made mixtures under the principles of specific vaccine treatment By accepting the mixed vaccines of commerce, the physician abandons reason and begins to grope in the dark, forgetting that "a multitude of remedies is the child of ignorance" His examination of patients tends to become more and more superficial, his diagnosis slipshod, and his treatment routine, without positive indications, and without individualization If more than one vaccine needs to be given, why not follow the simple and perfectly rational plan of mixing them at the time of injection or of injecting them separately?

As vaccine treatment became readily available by means of stock and mixed vaccines of all kinds, its use was extended to practically all forms of infection, acute and chronic, general and local, and even to conditions clearly not infectious in nature, regardless of whether or not there was any good reason to believe that benefit would come from efforts to stimulate the output of specific antibodies under all these circumstances As we look back it seems now as if special efforts were made "to hasten the use of the remedy while it still cured" As would be expected, the interpretation of the results often has lacked the discrimination and questioning which accompany the efforts of critical intelligence The great difficulties in the way of reaching sound conclusions as to the real value of a special therapeutic method — at best with an indirect and auxiliary action—in a great variety of infections that are subject to spontaneous improvements, and most of which as a rule are spontaneously curable, did not in all cases lead to proper caution in judging the apparent results of the routine and indiscriminate use of vaccines in this large field The observations have not been always trustworthy or the reasoning just The simple fact is that we have no reliable evidence to show that vaccines, as used commonly, have the uniformly prompt and specific curative effects proclaimed by optimistic enthusiasts and especially by certain vaccine makers, who manifestly have not been safe guides to the principles of successful and rational therapeutics

While uncertainty and disappointment have developed in regard to the usefulness of vaccines, this must be ascribed more to fault of exploitation than to fault of the thing exploited, for in the original field, restricted to subacute and chronic local infections under mechanical conditions that are favorable for healing, cautious observers, proceeding as nearly as possible in accord with the principles of immunity, have reached the conclusion that specific vaccine treatment may be of great auxiliary value in stimulating the defensive resources of the organism

That the beneficial action of specific vaccines in hastening recovery in subacute and chronic localized infections may result from increase of specific antibodies, as assumed, looks like a reasonable explanation, as the infecting germs may be so enclosed and walled off that antigenic substances in adequate quantities do not reach the centers of antibody production It is of course altogether possible that other factors also are concerned in the effects of vaccines, as, for example, stimulation of the leukocytic activity, which is subject to variation, liberation of nonspecific ferments, and protein fever, but until recently only scant attention was given to such possibilities According to this view of the nature of the action of vaccines, acute infectious diseases were regarded as not suitable for vaccine treatment because here the infecting germs, widely distributed in the body, would furnish all the stimulus needed to call forth an abundant supply of antibodies The original theory of vaccine treatment really furnishes no basis for the application of vaccines to acute infectious diseases and when, nevertheless, reports were made of striking effects from vaccines in acute disease, especially in typhoid fever and in pneumonia, we had no preconceived or readily available explanation to offer of the unexpected results This brings us to the consideration of the remarkable development during the last year or two of vaccine treatment of typhoid fever

While isolated instances of rapid improvement and even crisis ending in recovery are and have been ascribed to the injection of specific vaccines and also of semisecret culture filtrates in various acute infectious diseases, the true significance of such results in many cases remains doubtful on account of the variable spontaneous course of such diseases But in the case of typhoid fever at least, as I hope to make clear, the situation is different

Vaccine treatment of typhoid fever was practiced first so long ago as 1893 by Eugene Fraenkel, who gave subcutaneous injections of heated thymus broth cultures of typhoid bacilli apparently with benefit It had been found that this vaccine would protect animals against living typhoid bacilli, and Fraenkel wanted to determine whether or not it would modify the clinical picture of typhoid fever when injected during the attack The method received but little attention and save for interesting experiments of Petruschky and of Richardson it was not until about 1909 that reports began to appear of more or less favorable results from the subcutaneous injections of typhoid vaccines of various kinds The results were not striking and yet not without encouragement, as the intensity of the symptoms and the duration of the attack seemed to be reduced In a few cases rather quick cures followed as had been noted by Fraenkel also Then came the intravenous injection of the vaccine by Ichikawa (1912) and others with such noteworthy effects as to attract general attention and secure for the method prompt trial at many hands

At present it seems to be the opinion of almost all who have used the intravenous method of injection that by it the course may be modified and shortened and in a considerable number of cases even cure by crisis produced As it is very rarely that typhoid ends by spontaneous crisis — according to good authority in about 0 1 per cent of the cases — the occurrence of recovery by crisis in from 30 to 40 per cent after intravenous injection certainly cannot be ascribed to any chance spontaneous cure The striking immediate results of an effective injection are now well known Within half an hour or so a chill, often severe occurs with a rapid rise of the temperature, followed after some hours by a progressive fall, relaxation profuse perspiration, and rapid subjective and general improvement first the number of leukocytes falls, and then there is a rapid rise to 15,000 or more The subsequent course may be a permanent return to normal temperature and prompt recovery — crisis, a rise of temperature to the previous level and then a gradual fall to normal in a few days — lysis, or the attack may be resumed, running an apparently unmodified or somewhat milder course than before the injection When the attack is resumed, reinjection after a few days may cut it short, but it appears that if from two to three injections from three to four days apart have only temporary effect, no abortive cure need be expected

Crisis has been produced in typhoid fever by the injection not only of typhoid vaccines of various kinds, but also of colon vaccine, of mouse typhoid vaccine of meningococcus vaccine, and even of albumose Indeed, the specific nature of Fraenkel's results in 1893 was challenged promptly by Rumpf, who claimed the same results from the injection of products of pyocyaneus bacilli In other infections than typhoid, nonspecific products intravenously may cause acute critical reactions, as typhoid vaccines in paratyphoid fever colon vaccines in puerperal sepsis, pneumococcus and typhoid vaccines in erysipelas,[1] and typhoid vaccines in pneumonia[1] In normal persons the intravenous injection of typhoid vaccine may give a reaction much like that in typhoid fever, but a larger dose may be required I may mention, too, that in pneumonia intravenous injection of autolyzed pneumococci, prepared by Rosenow's method, may cause an immediate chill with rise and fall of temperature and fall and rise of leukocytes, in short, the same phenomenon as seen in the induced crisis in typhoid and followed in some cases by prompt recovery[1] The intravenous injection of protein substances appears to produce a reaction which closely resembles the chills and fever that occur naturally in the course of various infections We are reminded of reactions observed by Vaughan in his experimental study of protein fever and also of effects said to follow intravenous injections of nonprotein colloids for instance, gold

Whether or not the production of this kind of reaction is associated frequently with improvement and prompt recovery in other diseases than typhoid is not known Typhoid fever is the only disease which has been treated systematically by the new method and as yet specific vaccines have been used almost entirely In their admirable and thorough study of a series of fifty-three cases of typhoid, treated with Gay's vaccine Gay and Chickering[2] found that no permanent benefit resulted in 34 per cent, lysis with shortened course in 24 5 per cent, and critical cure in 41 5 per cent They report no alarming symptoms from the injections but others using different methods have reported instances of collapse, of hemorrhage and of hyperpyrexia with delirium and death, so that this treatment is not to be lightly undertaken

Gay would ascribe the rapid cure to the combined action of specific antibodies and the leukocytosis This view is supported by the facts observed by several that the most pronounced results have been obtained after the tenth day of the disease when the general reaction against the infection is fully developed, and that much less effect has been achieved in the incubation period As the same results may be produced in typhoid fever by nonspecific vaccines and even by albumose as by various forms of typhoid vaccines, although whether in the same percentages is not known, it is natural that other views should be presented Jobling and Petersen[3] find that in animals the intravenous injection of killed bacteria mobilizes nonspecific ferments, and they suggest that the effects of specific vaccines and other products in typhoid fever are due to the work of these ferments in destroying bacilli and in reducing toxic substances to nontoxic It has been suggested also that following the shock of the intravenous injection the organism passes into a refractory condition (antianaphylaxis) in which it ceases to react to the typhoid bacillus and its products These views, it seems to me, may serve as suggestions for more formal hypotheses to direct investigations for the purpose of learning more of the nature and the effects of the reaction as well as its therapeutic value

SUMMARY

If the presentations in this paper are trustworthy, it may be concluded that the general results so far from the routine use of commercial vaccines, polyvalent and mixed, have no value as evidence for or against the curative usefulness of vaccine treatment, and hence no value, either, with respect to the soundness of the theory on which vaccine treatment primarily has been developed

In subacute and chronic localized infections, the results appear to indicate that specific vaccines properly and skillfully used have value, quite likely because they increase the production of specific antibodies, as demanded by the theory, but probably also because they stimulate leukocytic and other activities

In typhoid fever and possibly also in other infectious diseases, the intravenous injection of specific vaccines and also of other substances may induce crisis and prompt recovery The mechanism of this action is not fully understood, but as it involves something more than or different from specific stimulation of the production of antibodies, it cannot be interpreted in terms of the current conception of the action of vaccines We are entering, therefore, a new and interesting development in the study and treatment of infectious diseases

THE DETERMINATION OF ALVEOLAR CARBON DIOXID TENSION BY A SIMPLE METHOD *

W McKIM MARRIOTT, M D

BALTIMORE

In acidosis the tension, that is to say, the effective concentration of carbon dioxid in the alveolar air, is diminished [1] By the determination of this tension the diagnosis of acidosis may be made, the degree of severity estimated, and the results of treatment followed The determination may be carried out in a few minutes' time and with no especial discomfort to the patient Two procedures are involved the collection of the alveolar air, and the analysis of the sample

COLLECTION OF ALVEOLAR AIR

The method of collection is essentially that of Plesch,[2] as modified by Higgins [3] A rubber bag of approximately 1,500 c c capacity[4] is connected by means of a short rubber tube to a glass mouthpiece [5] About 600 c c of air are blown into the bag with an atomizer bulb, and the rubber tube clamped off by a pinchcock The subject should be at rest and breathing naturally [6] At the end of a normal expiration, the subject takes the tube in his mouth, the pinchcock is released and the subject's nose closed by the observer The subject breathes back and forth from the bag four times in twenty seconds, emptying the bag at each inspiration The observer should indicate when to breathe in and out Breathing more frequently will not greatly alter the results At the end of twenty seconds, the tube is clamped off and the air analyzed The analysis should be carried out within three minutes' time, as carbon dioxid rapidly escapes through rubber

The foregoing procedure applies to patients who are capable of cooperating to some extent In the case of comatose patients, the initial amount of air in the rubber bag must be greater (1,000 c c at least), and the period of rebreathing prolonged to 30 seconds [7] This is necessary, as it is not feasible that the bag be completely emptied of air at each inspiration, and therefore a longer time is required for the carbon dioxid tension in the bag and in the lungs to become equal The initial amount of air in the bag should be such that it is at least one half and preferably as much as two thirds emptied at each inspiration Since comatose patients cannot hold the mouthpiece, some form of mask is necessary This may be a gas anesthetic mask[8] or such a device as described below for use with infants

A special mask has been devised for the collection of alveolar air from infants [9] It is made from the nipple of a wide mouth (Hygeia) nursing bottle and a piece of thin rubber tissue (dental dam) A sheet of the tissue (8 by 10 inches) is perforated in the center by a piece of hot metal or glass tubing of large bore The hole is stretched and pulled over the nipple and slipped down to the lower rim A small amount of rubber cement is applied to hold the tissue and nipple together A strip of adhesive plaster three-eighths inch wide is applied around the rim of the nipple so as to overlap the rubber tissue and hold it firmly in place The extreme tip of the nipple is cut off and a short glass tube, three eighths inch in diameter, inserted

> ‘In making a collection of alveolar air from infants a rubber bag of 500 c c capacity is connected with the mask and partially filled with air by means of an aspirator bulb The neck of the bag is closed off by a pinchcock or with the fingers, the mask placed over the nose and mouth of the infant and the rubber tissue closely drawn around the face so as to prevent the escape of air The mask should, if possible, be placed over the face just at the end of expiration Respirations are allowed to continue for from twenty-eight to thirty-two seconds, and at the end of an expiration the neck of the bag is closed off and the mask removed from the face. We have found that it is necessary that the infant should be breathing quietly for one minute previous to the collection of the air sample, as vigorous crying, just before the mask is put on, leads to a lowering of the carbon dioxid tension, as determined, by several millimeters Crying during the collection of the sample almost invariably occurs and facilitates mixing of the gases The effect is to raise the tension somewhat if crying is very vigorous, but not to such an extent as to be significant The initial amount of air in the bag must be such that during inspiration the bag is from one-half to two thirds empty, but never completely collapsed The amount of air required for infants under 1 year of age varies from 250 c c to 400 c c”

The mask described above for use with infants may be very conveniently used for the collection of alveolar air samples from dogs The animal's nose is inserted into the mask and the rubber tissue drawn closely around the muzzle The time of a collection need not exceed twenty-five seconds

For analysis of the air samples, the apparatus required comprises eight test tubes, containing standard phosphate solutions, a standard bicarbonate solution, a small test tube, a glass tube or pipet drawn out to a capillary point, and a box for color comparison

[illegible] a hot water bag answers very well If [illegible] be closed by a rubber stopper carrying [illegible] inch in internal diameter [illegible] tubing with rounded edges, 1½ inch [illegible] external diameter

[illegible]inst is a deep, voluntary inspiration [illegible] this causes too low a determination

[7] The bag is clamped off at the end of that expiration occurring nearest to thirty seconds, as no great error is introduced by prolonging the time of rebreathing by two or three seconds

[8] Some advantage may be gained by inserting a large three way stopcock of metal or glass between the mask and the bag When such a stopcock is used, the mask is first put in place on the patient's face with the cock so turned that he breathes the outside air for a few respirations At the end of an expiration the cock is quickly turned so as to bring the bag and the mask into connection

PRINCIPLE OF THE METHOD OF ANALYSIS

The method depends on the fact that if a current of air containing carbon dioxid is passed through a solution of sodium carbonate or bicarbonate until the solution is saturated, the final solution will contain sodium bicarbonate and dissolved carbon dioxid The reaction of such a solution will depend on the relative amounts of the alkaline bicarbonate and the acid carbon dioxid present This, in turn, will depend on the tension of carbon dioxid in the air with which the mixture has been saturated and *will be independent of the volume of air blown through provided saturation has once been attained* High tensions of carbon dioxid change the reaction of the solution toward the acid side Low tensions have the reverse effect, hence the reaction of such a solution is a measure of the tension of carbon dioxid in the air with which it has been saturated

The reaction of such a solution may be determined by adding to it an indicator such as phenolsulphonephthalein[10] which shows over a considerable range of reaction definite color changes A certain color indicates a certain reaction

Solutions of a given reaction may be prepared by mixing acid and alkaline phosphates in definite proportions Such solutions may be kept unaltered for long periods of time and can be used as standards for comparison

PREPARATION OF STANDARD PHOSPHATE SOLUTIONS[11]

Fifteenth molecular acid potassium phosphate Of the pure, recrystallized salt (KH_2PO_4), 9 078 gm are dissolved in distilled water, 200 c c of 0 01 per cent phenolsulphonephthalein solution are added, and the whole is made up to 1 liter

Fifteenth molecular alkaline sodium phosphate The pure, recrystallized salt (Na_2HPO_4 $12H_2O$) is exposed to the air for from ten days to two weeks, protected from dust Ten molecules of water of crystallization are given off and a salt of the formula Na_2HPO_4 $2H_2O$ is obtained Of this salt, 11 876 gm are dissolved in water, 200 c c of 0 01 per cent phenolsulphonephthalein solution are added, and the whole is made up to 1 liter The solutions are mixed in the proportions indicated in the tabulation

PROPORTIONS IN WHICH SOLUTIONS ARE MIXED

Mm	10	15	20	25	30	35	40	45
Acid potassium phosphate c c	17 8	25.2	31 0	35 7	40 5	45 0	47 0	50 2
Alkaline sodium phosphate c.c	82 2	74 8	69 0	64 3	59 5	55 0	53 0	49 8

The solutions thus made are put in small test tubes (a convenient size is 10 by 75 mm) and stoppered or sealed off These standard tubes should be kept in a dark place when not in use

The standard bicarbonate solution is prepared either by weighing out 0 530 gm of desiccated sodium carbonate or by measuring accurately 100 c c of tenth normal sodium hydroxid into a 1 liter volumetric flask Two hundred c c of 0 01 per cent phenolsulphonephthalein are added, and the whole is made up to the mark with distilled water Carbon dioxid from a cylinder or from the lungs may be passed through this solution to convert the alkali into bicarbonate, or the solution may simply be used as it is, as the alveolar air that will be blown through the solution subsequently will accomplish the same purpose

The comparison with the standard colors is conveniently made with a box similar to that used with the Sahli hemoglobinometer, but containing three instead of two holes It is a small, flat box of blackened metal, 55 by 45 by 20 mm , backed with opal glass and with three slits open on the front By the use of this device, slight color changes may be easily detected, and the temperature of the tubes is not raised by the heat of the hands In addition, the whole device, with tubes, may be immersed in water at a given temperature

All of the standard solutions used in this method should be kept in glass which does not readily give off alkali, that is to say, such a glass as "Jena," "Non-sol" or "Pyrex" A small amount of toluene or thymol added to each solution serves to prevent the growth of molds

TECHNIC OF THE METHOD OF ANALYSIS

In analyzing a sample of air, about 2 or 3 c c of the standard bicarbonate solution are poured into a clean test tube of the same diameter as the tubes containing standard phosphate solutions, but from 100 to 150 mm long Air from the bag is then blown through the solution by means of a glass tube drawn out to a fine capillary point, until the solution is saturated, as shown by the fact that no further color change occurs[12] The tube is stoppered and the color immediately compared with that in the standard tubes By interpolation, one can readily read to millimeters Color changes are not quite so sharp above 35 mm as at the lower end of the scale but here changes are of less significance In making the color comparisons, the solution being compared is placed between the two standards which it most nearly matches When there is doubt as to whether the color of the solution is higher or lower than one of the standards, changing the order in which the tubes are placed in the comparison box will generally make the relationships clear

The standard solutions described are so prepared as to give correct results when the determination is carried out at a temperature of from 20 to 25 C (from 68 to 77 F) When the room temperature is considerably higher or lower than these points it is advisable to immerse the tubes in water at approximately 25 C during the blowing They may be removed from the water for the color comparison, however, provided this is quickly made The differences due to the ranges of temperature occurring under ordinary circumstances are practically negligible

No correction for barometric pressure is required as from the nature of the determination barometric fluctuations are self-corrective Variations in the temperature of the subject are never great enough to affect the value as much as 1 mm , and therefore may be neglected

RESULTS

If the simple conditions described above for the collection and analysis of air samples are complied with, duplicate determinations usually agree within 2 mm More than one determination should be made in every instance, especially in confirmation of a low tension, since errors in the technic of collection of the sample lead to too low rather than to too high results

---

[10] Levy R L Rowntree L G, and Marriott, W M A Simple Method for Determining Variations in the Hydrogen Ion Concentration of the Blood Arch Int Med September 1915 p 389

[11] Standardized phosphate mixtures, sealed in tubes the standard bicarbonate solution, tubes color comparison box and other accessories may be obtained from Hynson Westcott & Co Baltimore

[12] If the operator first blows his own breath through the solution so as to bring it into approximate equilibrium with alveolar air saturation may be accomplished with as little as 100 c c of air from the bag blown through during thirty seconds The same bicarbonate solutions may be used for repeated determinations

In the case of failure of successive determinations to agree, the fault is much more likely to lie in the collection than in the analysis of the sample

In normal adults at rest, the carbon dioxid tension in the alveolar air, determined as described above, varies from 40 to 45 mm Tensions between 30 and 35 mm are indicative of a mild degree of acidosis When the tension is as low as 20 mm, the individual may be considered in imminent danger In coma, associated with acidosis, the tension may be as low as 8 or 10 mm In infants, the tension of carbon dioxid is from 3 to 5 mm lower than in adults

Conditions other than acidosis may affect the carbon dioxid tension Stimulation of the respiratory center leads to increased pulmonary ventilation and a consequent lowering of the alveolar carbon dioxid tension Such stimulation may be brought about by caffein,[1] and possibly also by intracranial lesions The respiratory center may be depressed by morphin, and as the result of certain[13] infections This leads to an increased carbon dioxid tension Changes in the excitability of the respiratory center, however, are but rarely great enough to affect significantly the composition of the alveolar air

"Alveolar" air collected as described above is essentially air which has come in equilibrium with the venous blood in the pulmonary capillaries The tension of carbon dioxid is approximately that in the venous blood "Alveolar" air collected by the Haldane or Friederecia methods is air which has come in approximate equilibrium with the arterial blood and hence is of a carbon dioxid tension from 10 [illegible] per cent lower

Changes in the pulmonary epithelium such as would prevent the air in the lungs from coming in equilibrium with the blood in the capillaries would, of necessity, affect the composition of the alveolar air Since very little is known as yet regarding the exact effect of such changes, one is hardly justified in drawing conclusions regarding acidosis from the composition of the alveolar air in patients with pulmonary affections[13]

Earliest Connection of Plague with Rodents—The Biblical use of the word "plague" is, like its medieval use, more often than not, in the general sense of a pestilence or epidemic disease, rather than in the specific sense of the disease now known as bubonic plague The expression "a plague of leprosy" is a common one and there is no reason to suppose that any of the ten plagues of Egypt were of the character of the malady now under discussion But in a few instances there are some grounds for believing that the disease mentioned was in truth bubonic plague and no other The most remarkable reference is found in 1 Samuel iv, v, vi, where the Philistines were smitten with emerods or tumors in their secret parts The Ark was sent to Gath, then to Ekron, and the plague followed it In the meantime there seems to have been a veritable plague of mice In the ordinary version there is only incidental reference to "the mice that mar the land" (1 Sam vi, 5), but in the Septuagint version the references are more distinct, "in the midst of the land thereof mice were brought forth, and there was a great and deadly destruction in the city," and further (1 Sam vi, 1) that 'their land swarmed with mice" The Philistines returned the Ark to Beth-shemesh, with golden images of the tumors and of the mice, but still the plague followed it, and no less than 50 070 persons perished. This is the earliest reference connecting bubonic plague with rodents, and it has taken three thousand years to invent the rat flea and its specific bacillus as agents for spreading the disease—John W Fries, *Southern Medical Journal*

SOME MODERN VIEWS OF SYPHILIS OF THE NERVOUS SYSTEM

ARCHIBALD CHURCH, MD
CHICAGO

About forty years ago when Fournier had the temerity to intimate that in the great majority of cases of locomotor ataxia syphilis was the cause, Ricord, his confrère and the most prominent syphilographer of the day, said that Fournier had taken on himself a very bad burden A few years later, when Erb in Heidelburg assumed responsibility for a similar point of view, medical Germany was mobilized against him So the matter stood for some years and was threshed out with acrimony on both sides

Later, Negeotte brought forth his epoch-making observation, that in locomotor ataxia there is invariably some evidence of inflammation in the meninges of the cord Following the practice of Quincke, the routine examination of the spinal fluid determined the presence of cellular peculiarities invariably present in cases of locomotor ataxia as well as in those of general paresis General paresis and locomotor ataxia from that time have proceeded side by side in the estimation of the medical profession as either being caused by syphilis or being intimately associated with syphilitic processes affecting the neural axis

Then came Schaudinn with the discovery of the spirochete as the actual cause of syphilis, closely followed by Wassermann, whose reaction proved the essential fact of syphilis in these diseases The matter has been finally and positively clinched through the discovery, by Moore and Noguchi, of the spirochete in the lesions of tabes and general paresis Now we are in a position to say that locomotor ataxia and general paresis are manifestations of syphilis We should no longer use the terms "parasyphilis" or "metasyphilis," coined by Fournier and his followers, because we are dealing with actual syphilis — with late syphilis

PREVALENCE OF SYPHILIS

For a great many years writers and teachers have contended that there was wide prevalence of syphilis, especially in urban populations Approximations, based on clinical histories and objective signs, both in private practice and in hospitals, indicated that about 20 to 25 per cent of all adult males were syphilitic If this is true, the question as to how many of this tremendous army of syphilitics are subsequently to develop syphilis of the cerebrospinal system is of the utmost importance Only since we have had the advantage of the Wassermann reaction as a means of diagnosis have we been in a position practically to solve the problem

The report of Vedder[1] on syphilis among recruits is instructive The examinations on which this report is based were made at Fort Slocum, near New York, and at Jefferson Barracks, near St Louis In New York the majority of those applying for admission to the army were of city extraction and habits, while those in St Louis came largely from the surrounding country districts Of all who applied, only those were accepted who were physically fit, and those who showed evidences of syphilis or gave a history of recent syphilis were excluded Out of the entire number applying, only 17 per cent were accepted, that is to say 83 per cent. were rejected. In the 17 per cent. selected the Wassermann test of the blood, made apparently with scrupulous care and checked by competent associate observers, indicated that 16.7 per cent. were syphilitic. The astonishing and alarming fact stands out that the rural population at Jefferson Barracks seemed to have nearly as high a percentage of syphilis as the urban population examined at Fort Slocum. We are therefore clearly within conservative lines when we estimate that one man in every five is syphilitic.

---

[1] Vedder Prevalence of Syphilis in the Army Surg Gen Bull 8, June 1915

PREVALENCE OF NERVOUS SYPHILIS

Now the question is, if so many people are syphilitic, how many will have syphilis of the nervous system? Examinations of the spinal fluid in cases of primary and secondary syphilis, according to Finger, give positive reaction for the various tests in 70 per cent. of cases; that is to say, in early syphilis the spinal fluid shows an actual syphilitic process in the nervous apparatus seven times in ten. Altmann and Dreyfuss found this to be true in 82 per cent. of cases. Still further, Hoffmann, Nichols and Steiner have found that, in 15 per cent. of cases in the primary and secondary stages, before changes can be found by Wassermann or other reaction, these spinal fluids are infectious and the disease can be transmitted by their inoculation.

Here emerges the astounding fact, that every case of syphilis from the very first is a case of cerebrospinal syphilis, of nervous syphilis, and that no case of syphilis runs its course, even for a short time, without producing changes in the neural apparatus. Such changes formerly were considered to be a late complication. The ectodermal origin of the neural axis may explain the early involvement of these tissues by a disease marked preeminently by skin lesions.

Thanks to the newer serologic tests, we are awakened to the fact that nervous syphilis has a much wider clinical territory than was even suspected. For instance, Collins,[2] excluding tabes, general paresis and the usual forms of cerebrospinal syphilis, is able to tabulate 245 cases encountered within a short time in his division at the New York Neurological Institute. These syphilitic cases were recognized only by means of the blood and spinal fluid investigations.

FREQUENCY OF TABES AND GENERAL PARESIS

What is the frequency of the late syphilis, which we formerly called parasyphilis or metasyphilis, of tabes, optic atrophies and general paresis?

White, in an examination of 1,016 cases of syphilitic men, found these late syphilitic manifestations in about 1 per cent. Pick and Bandler found paresis in 2.12 per cent. But the most significant statistics that I have found are those tabulated by Mattuschek and Pilcz. They have the detailed histories of 4,134 Austrian army officers who were infected with syphilis between 1880 and 1890, and these cases, which were complete in every detail and brought down to the year 1912, were then reviewed. As you can understand, in the Austrian army the records are reliable and complete, and after such a period of time they would justify definite deductions. Out of this large number, over 4,000 syphilized men, examined twenty-two years after the last of them were infected, Mattuschek and Pilcz found that 4.67 per cent. had developed paresis, more than 1.5 per cent. had developed tabes, or 6.27 per cent. had developed one or both of these diseases. Through all the usual manifestations of syphilis, 20 per cent. of the 4,134 had greatly abridged or lost their lives.

There is, apparently, a peculiar difference in the susceptibility of men and women to the development of these late forms of syphilis. Fischer examined 1,178 syphilitic men and found 3.7 per cent. paretic, while in 888 women he found 0.5 per cent.; that is to say, women are apparently less susceptible to tabes and paresis than are men. But perhaps an explanation of this peculiar sex variation can be found, and I will revert to the matter a little later.

VARIATIONS OF THE SYPHILITIC ORGANISM

It is an interesting fact that Schaudinn was not a physician but a zoologist. The discovery of the spirillum of syphilis was, in a sense, accidental, in that Schaudinn was selected, in conjunction with Hoffmann, by a committee of the German Academy of Sciences, to investigate the contention of Siegel, that he had found a certain organism, the *Cytorrhyctes luis*, in syphilitic lesions and claimed it to be the cause of syphilis. It was established that this organism has nothing at all to do with syphilis, but it plays an important role in having led to the detection of the spirochete. Schaudinn had been deeply interested in the spirilla of animal diseases, in African sleeping sickness and in the relapsing fevers, and with a mind saturated with the subject, he turned his attention to syphilis, naturally first looking for those forms of life with which he was on familiar terms, and he shortly detected the *Spirochaeta pallida*.

This spirochete is not the simple animal that was first supposed, but is capable of great variations in character and in clinical manifestations.

VARIATIONS IN VIVO

The spirochete presents variable strains. It has not the simplicity of the bacteria, although, thanks to Rosenow we now look on bacteria as capable of great morphologic and clinical differences.

Clinically, for a long period of years it has been recognized that syphilis is not always the same thing, and it has been known to clinicians that there is a variety of syphilis which might be called nervous syphilis. The French observers have been particularly active in gathering data on this point of view. I remember one report concerning five young soldiers who were syphilized from the same source at the same time, four of whom developed general paresis and one developed locomotor ataxia.

A more interesting case is mentioned incidentally by Erb, but was first published by Lavelle. It is the tragic story of a Martha X., who in 1870 was the mistress of a medical student who died in 1873 of cerebral syphilis. In 1871 she transferred to a second medical student, who afterward married and had healthy children, but died in 1880 of general paresis. In the following year she took up with a third student, who also later had healthy children in wedlock, but died in 1882 of general paresis. Then a chemist fell under her spells, and he died in 1890 of general paresis. He was followed by an engineer, who in 1893 died of general paresis. An interesting point here is, that the first victim died of cerebrospinal syphilis and his successors perished from general paresis, a clinical variation that is to be correlated with spirochetal variation.

---

[2] Collins: New York Med. Jour., 1916, ciii, 389.

Clinicians have seen cases of locomotor ataxia in husband and wife, and all clinicians in the field of mental disease have seen husband and wife present general paresis Conjugal syphilis, conjugal general paresis, conjugal tabes, and conjugal optic atrophy are common terms In these cases generally the wife has contracted the disease in wedlock from her husband In nearly all such cases, as is a common observation in the syphilis of married women, there is no history of a primary lesion, and secondaries have been slight or entirely unobserved The wife has contracted a syphilis of a modified character, in other words, the spirochete has undergone variation in vivo

Herein may be the explanation of the reduced incidence of tabes and general paresis in syphilitic women The conjugal cases, however, may indicate that syphilitic infection is possible in very late stages of syphilis, and then it produces a similar form of disease As a matter of fact, even the unmarked wives and children of paretics and tabetics will usually be found to be Wassermann positive

Ehrlich agreed with the view that spirochetes produce self-destructive antibodies in the human organism A few of the original strain, of superior vital qualities, perhaps, are able to persist in spite of the antagonism of the antibodies, and they propagate a second strain, which in its turn arouses the forces of resistance, and so on ad infinitum Finally, a strain is evolved which is apparently of a lowered fecundity, but of increased resistiveness, and the condition then tends to come to a standstill In the final stage probably the organism acquires an immunity to the usual remedies Here is possibly an explanation of the fact that in locomotor ataxia and general paresis mercury and the iodids are of much less value than in the conditions which precede, such as cerebrospinal syphilis, the arteriomeningeal lesions, and the ordinary manifestations of the tertiary stage Indeed, syphilitic lesions marked by gummy processes rarely are followed by the so-called parasyphilitic disorders In this clinical observation we see the manifestation of another variation of the spirochete

VARIATIONS IN VITRO

Variation of the organism has been confirmed by experiments in the laboratory Noguchi found that the spirochetes obtained from the brains of general paretics required for their development and propagation about sixty to eighty days, Graves of St Louis, using the blood of general paretics, found that he could produce syphilitic lesions in rabbits by inoculation, but that it required about sixty days, and both these investigators found that with spirochetes obtained from early stages of syphilis three or four weeks were sufficient The late-stage organism had clearly undergone a differentiation

Today in Washington, in the laboratory of the Army Medical School,[3] the investigators can produce several arieties of spirochete They can breed a variety hich will produce a hard chancre, or a variety which ll produce a chancre lacking the old hunterian chareristics of a saucerlike, indurated base They can duce a spirochete which will give a rich muconeous efflorescence, or a spirochete which will be in cutaneous manifestations, with a tendency to [illegible] influence on the nervous system Perhaps reach a time when, if we can determine the rnal the infection of a syphilitic patient, the stage of the disease and its characteristics in the carrier, we may be able to draw some conclusion as to the course that lies before the patient, and the nature of the clinical history which he may be expected to run

What of the various methods of intracranial, intraspinal, intravenous, and combined applications of the arsenicals and mercurials? I must admit that all of these measures thus far have not enabled us to cure or positively arrest locomotor ataxia or general paresis In those cases in which the lesions have not reached the stage of latest syphilis, those in which the disease falls especially on the vessels and the meninges, the prospects of cure are of the very best It is essential in the conduct of such treatment that we be guided, not by the Wassermann in the blood, but by the condition of the cerebrospinal fluid No man, in my estimation, is giving his patient the best treatment, or even the proper treatment, who withholds the administration of these remedies before he has obtained, for a period of years, negative results by the Wassermann, the other accepted tests, and the cytologic count in the spinal fluid The granting of marriage certificates to those who have had syphilis should not turn on the examination of the blood by the Wassermann method, but on careful examination of the spinal fluid

The problem of treatment appears not to be one of the surgical or mechanical administration of the old or new remedies, but the discovery of some agent particularly biocidal to the organism in its latest variations

RECURRENT GENERALIZED HERPES OF INFECTIOUS ORIGIN

REPORT OF A CASE *

FRANK COHEN, M D
Associate in Serology and Adjunct Pediatrist, Lebanon Hospital
NEW YORK

This report of a case of generalized herpes simplex that was recurrent over a period of two years will undoubtedly show its infectious origin This type of herpes is rare, and the observations made offer suggestions as to the etiology of the more common herpes simplex

Cases of herpes may be roughly divided into three groups Though in all three groups the skin lesions show a necrosis and exudation of varying intensity, these and other pathologic findings are most pronounced in the herpes zoster group Von Barensprung[1] and others described changes in the posterior root ganglion in herpes zoster, but it remained for Head and Campbell[2] to describe these changes in detail They found, in the ganglion of the posterior root of a part corresponding to terminal skin lesions, changes of acute degeneration, that is, exudation of round cells and hemorrhages, and destruction of cells and fibers They found acute degeneration and sclerosis in the posterior nerve roots, in the peripheral nerves and the posterior columns of the cord

The recent work of Rosenow and Oftedal[3] has

[1] Von Barensprung Annalen d Charite Krankenh, ix, *1861*

[2] Head and Campbell Brain *1900*, xxiii

[3] Rosenow, E C and Oftedal, S The Etiology and Experimental Production of Herpes Zoster, The Journal A M A June 12 1915 p *1968*

added much to our knowledge of herpes Streptococci were isolated from removed tonsils, and from pyorrheal pockets and spinal fluid of herpes zoster patients, these were injected into animals with resulting lesions of herpes and changes in the vagus and sympathetic ganglia Gram-staining diplococci and diplococci in chains were found in and about the ganglia Other streptococci or those isolated from tonsils or elsewhere after the patient is cured, do not manifest this similar elective localization when injected into animals The cultures from peripheral lesions were negative This work appears to be confirmatory evidence of the infectious origin of herpes zoster

In a second group of herpes, those due to a known toxic or infectious agent like changes have been described in the posterior root ganglion Acute inflammatory changes in the gasserian ganglion have been described when herpes occurred during cerebrospinal meningitis[4] pneumonia,[5] arsenic, carbonic oxid poisoning, etc Sunde[6] found a gram-positive diplococcus in the gasserian ganglion of a man with herpes who died of pneumonia

In these two classes of herpes, herpes zoster and the toxic or infectious cases, the lesions of the nervous system and the microbic origin are established

On the other hand in still another group, that of herpes simplex, there is no direct evidence of changes in the ganglia Heretofore no micro-organism has been found in the terminal lesions and there has also been absence of other evidence of the infectious nature of herpes simplex

In my case of generalized herpes simplex, the causative organism — a streptococcus — was isolated It is termed 'simplex" because it accompanied no infectious disease, it was due to no known toxic poison, nor was it a herpes zoster

The case is of special interest because of (1) its recurrence over a period of two years, (2) the isolation of the causative organism, streptococcus, (3) its cure by vaccine therapy

Much information and data were kindly furnished by Dr M Salzer of Cincinnati, who treated this patient several months before she was seen by me, and to whom my thanks are due Dr Berghausen of Cincinnati made the original cultures and vaccine

REPORT OF CASE

Mrs X., aged 30, past history negative, for over two years had been having almost continuous crops of herpetic eruptions The parts chiefly affected were lips, nose, both ears, chest, both wrists, occasionally the leg and forearm The lesions consisted of vesicles, very fine to pinhead in size, on a base that was red and swollen Contents of vesicles were clear and would dry up with practically no scaling

A typical attack would be preceded by much itching and burning and swelling of the lips There would be chilly sensations down the spine, profound depression of spirits and total loss of appetite Then numbers of fine vesicles would appear on a reddened base on the much swollen lips These would be followed by lesions on the nose ears and elsewhere Itching and burning continued throughout

Physical Examination—The patient looked thin and anemic, she had lost about 12 pounds in weight There was a marked lateral curvature of the spine All organs were normal Temperature and pulse rate were normal Blood examination showed a secondary anemia, otherwise negative The Wassermann was negative Roentgen-ray examination of the chest, abdomen head—sinuses and teeth—was negative There was very little tonsillar tissue

Special efforts were made to locate the source of infection in the tonsils, teeth or sinuses without success

Blood culture was negative Cultures, however, made on blood agar of material aspirated from vesicles, and probably some from tissue about the vesicles showed a streptococcus in long chains From subcultures a vaccine was made

The patient was injected with this autogenous vaccine in doses ranging from 100 million to 1 billion bacteria Injections were given every three or four days Reactions followed injections, outbreak of herpetic lesions, and rise of temperature with larger doses After five weeks of this treatment by Dr Salzer, the patient came under my care

The disease had now lasted over two years, and protracted stays in bed were the only means which seemed to check attacks All the usual methods of treatment, external, internal hypodermic, change of climate etc., were tried

It seemed to me that, as there was some amelioration in the symptoms, gain in strength and lengthening of intervals between attacks it would be best to continue the only measure that brought relief outside of rest, the vaccine method of treatment It was essential to use the patient's own organism as vaccination with other strains of streptococci would not according to Rosenow's findings, have produced the antibodies of her particular strain In an endeavor to do away with the negative phase and in order to give larger doses I sensitized the autogenous vaccine

Sensitization was performed by adding to every cubic centimeter of autogenous vaccine 2 c c of a polyvalent antistreptococcus serum This was placed in a thermostat at 37 C (98 6 F) for twenty-four hours and shaken frequently The preparation was centrifuged The bacteria were then washed free of serum with sterile saline After testing sterility the bacteria plus antibody, were ready for injection

Six injections of this sensitized autogenous vaccine were given in one month The dose was increased from 200 million to 2 billion bacteria There were no local reactions until the two largest (1½ and 2 billions) were reached, when there was a slight outbreak of the eruption There were minor constitutional reactions at times, such as depression of spirits chilliness and loss of appetite following injections, but a gain in well-being strength and in weight was almost immediate One more injection quickly controlled a slight outbreak that occurred about a month after treatment had been discontinued

Five months have elapsed since, and there has been no recurrence, meanwhile the patient has gained 11 pounds in weight, and she is strong and happy

CONCLUSIONS

The isolation of the micro-organism from the skin lesion, the institution of a negative phase by its injection, with skin manifestations, and the cure, unattainable by any other means than the increase of immunity for the streptococcus by the injection of streptococcus vaccines, are all direct evidence of the infectious nature of this herpes It is therefore a step toward proving the infectious origin of herpes simplex, and another step in the direction of showing the common origin of all herpes

SOME OF THE SURGICAL ASPECTS OF PAINFUL BACK

WILLIAM E SHACKLETON, M D
CHICAGO

I wish to consider a condition equally as important as arthritis of the spine or sacro-iliac subluxation, although it is not so common It is a condition more common than is generally supposed, and equally as potent a factor in the causation of sciatica, scoliosis and painful back I refer to a class in which, in the past, operation has been performed for various supposed pelvic and abdominal conditions, also for cord tumors and Pott's disease, or they have been treated medically for lumbago, rheumatism and sciatica without relief

The cause of pain and disability in these cases is an anatomic variation in the shape or size of the transverse process of the fifth lumbar vertebra, sometimes spoken of as the lumbar rib A study of the roentgenograms of the lumbar and pelvic region shows that variation in the size and shape of the lumbar process occurs as frequently as anatomic variations in other parts of the body Adams[1] reports a study of fifty consecutive cases in the Massachusetts General Hospital in which careful Roentgen examinations were made Of these, forty-four cases showed bony defects in the sacrum or fourth and fifth lumbar vertebrae Seven of these showed an anomaly of the fifth lumbar inferior articular process, and two others showed an enlargement of the transverse process

In the majority of cases the condition is undoubtedly an acquirement during the years devoted to hard labor, especially in people following occupations requiring an unnatural posture, such as woodchoppers, automobile repairmen, washerwomen, sailors, etc For this reason it is more common in middle adult life and among the male sex, although Kleinschmidt[2] reports a case in which the symptoms first appeared at the age of 5, and Adams[3] one case in a girl of 16 who was operated on It is evident that while occupation is the chief contributing cause of enlargement of the fifth lumbar transverse process, it is not the only one Meisenbach[4] reports a case of fracture with a large callous formation, as does Ferrall[5] Infectious diseases, especially syphilis, are probably an etiologic factor Denuce[6] reports a case of enlargement, as shown by the Roentgen ray, associated with sciatica, in which the patient recovered under antisyphilitic treatment

The factors involved in the production of pain are apparently not the same in all cases There are several possible ways in which the pain may be caused, one by impingement of the process on the ilium separating the sacro-iliac joint The transverse process may act as a fulcrum separating the sacrolumbar joint There is a third possibility, as indicated by the case of Adams,[3] in which an erosion of the ilium occurred as the result of constant friction Irritation may set up a hyperplasia of the surrounding soft tissues which might include the nerve, or direct pressure on the nerve itself, as a cervical rib presses on the brachial plexus, illustrated by Kleinschmidt[2] and by my own case

The roots of the fifth lumbar nerve originate from the spinal cord between the levels of the twelfth dorsal and first lumbar vertebrae They enter into the formation of the cauda equina, and combining, take exit through the intervertebral foramina between the last lumbar vertebra and the sacrum, as the fifth lumbar nerve The anterior primary division of the fifth nerve descends over the ala of the sacrum and divides into the anterior and posterior parts, which are joined by corresponding parts of the fourth lumbar nerve The two resulting trunks are known as the lumbosacral cord The anterior part contributes to the formation of the tibial and the posterior part to the peroneal nerve The lumbosacral cord lies directly on the bones of the linea innominata, whereas the other portions of the sacral plexus lie on the pyriform muscle

The fifth lumbar nerve, through the sacral plexus, supplies sensory fibers to the outer side of the leg, to the inner side of the dorsum of the foot, the back of the leg, the inner and outer sides of the great, second and third toes, and the inner side of the fourth toe It sends motor fibers to the gluteus maximus, minimus and medius, the short head of the biceps, the semimembranosus and semitendinosus, the long head of the biceps, and a number of muscles on the back of the leg, the inner and outer sides of the front of the leg, and the inner side of the sole of the foot

The remarkable fact has been noted (Oppenheim[7]) that in cases in which compression or other injury affects the sciatic in the pelvis, the paralytic symptoms are most marked in the peroneal nerve, presumably because its fibers lie directly on the bone

In a careful search of the literature I have been able to find but twenty cases reported Six of these patients were not operated on Of these, four cases (6 and 14) were lost track of The other two, including the case of Denuce,[6] mentioned above, and a case of Calve's[8] showed improvement Fifteen patients were operated on with the results given in the accompanying tabulation

In addition to these I wish to report three cases One of the patients was operated on by Dr P B Magnuson, and one by myself The third patient refuses operation at the present time, but is still under observation In Case 1 the history was furnished by Dr Magnuson

Case 1 —*History*—Mrs S W, a housewife, aged 35, white, was admitted to Wesley Hospital, Jan 13, 1915 Her family history was negative, as was also the menstrual history, she had had no past illness She had two children, both normal births

Eight years ago, following the birth of her last child, the patient noticed pain on the left side over the left upper sacral region which radiated down over the sciatic nerve back of the left knee This was exaggerated by bending over the washtub or lifting This pain has continued in greater or less severity, depending on the labor performed, until the present date

About six years ago the patient noticed a mild pain on the right side in the upper sacral region, but about 1½ or 2 inches further away from the spine than the pain on the left side which greatly increased until at the present time she is unable to stand erect, leaning toward the left Flexion is limited toward the right, flexion forward relieves the pain somewhat on the right side, but increases it on the left side There is no pain radiating down the sciatic nerve on the right side It is constant and continuous in one spot Roentgenoscopy reveals a long lateral process on the fifth lumbar vertebra on the right side impinging against the crest of the ilium at the point which corresponds to the area of the intestines and the seat of pain on the right

The patient has spent the last six months in bed The back is flat in the lumbar region, and there is some rotation of the spine toward the left

Operation and Result—The patient was operated on Jan 21 1915 A longitudinal semilunar incision with the convexity toward the right was made from the spine The lumbar muscles were pulled aside, and the fifth lumbar lateral process was exposed deep down under the muscles An attempt was made to introduce a periosteotome between this process and the ilium which was unsuccessful The process impinged and apparently was adherent to the crest of the ilium With a Fenger dissector bent under the process at the base a thin bladed chisel was driven down through it transversely It was then grasped with an 8 inch forceps and pulled out The left sacro-iliac joint was then exposed, the ligaments cut, and with a lever this joint was pried in such a way as to pull the sacrum back and pry the ilium forward, after which the ligaments were sutured and the wound closed

The patient remained in bed lying on her face or side, for six weeks, and according to her statement she had less pain following the operation than she had had at any time for the last six years At the end of six weeks a straight, front laced corset with heavy band and buckle around the hips was applied, and the patient was allowed to stand on her feet at the end of eight weeks She went home during the ninth week, and when she was last seen by the operator, about five months after leaving the hospital, she had gained 20 pounds in weight, was doing her own housework, including the washing, said she had not had any pain in her back, that she was no longer nervous as she had been before the operation and from her own statement was completely cured of her trouble

Case 2—*History*—H M, man, referred for operation by Dr M T Goldstine, entered my service at Wesley Memorial Hospital, Aug 4, 1915 He was by occupation a butcher, aged 37, married Family and past history were negative

For six months previous to entering the hospital the patient had complained of aching pain over the right hip and right lower lumbar region The pain gradually increased in severity until for a period of six weeks before entering the hospital he was unable to assume an upright position At this time the pain radiated downward and into the peroneal group of muscles He consulted physicians who treated him for arthritis and lumbago without any improvement Even under immobilization the condition became worse Physical examination showed a well developed man of about 170 pounds He was unable to stand erect, there was marked lateral curvature of the spine convex to the right, slight atrophy of the gluteal muscles, and marked atrophy of the peroneal group There was tenderness just above the right sacro-iliac joint, and rigidity of the lower vertebrae

The head, neck, chest and abdomen were negative The right knee jerk was exaggerated, the left normal, other reflexes normal There was tenderness over the peroneal muscles of the right leg

The laboratory findings blood, urine and Wassermann test were negative A roentgenogram showed a large bifid, transverse process on the left side of the fifth lumbar vertebra The right transverse process was a straight prolongation pointing outward and downward, impinging on the sacro-iliac articulation

Operation and Result—A curved incision was made over the lower lumbar and sacral region to the right of the median line The lumbar muscles were split along the outer edge by blunt dissection and the transverse processes of the fourth and fifth lumbar vertebra exposed A curved periosteotome was used to free the anterior surface of the process pressing the nerve trunk gently out of the field During this maneuver one marked contracture of the leg occurred showing pressure on the nerve The instrument was then pressed up tightly against the spine and placed in the hands of an assistant with instructions to hold tightly against the process while with a hammer and chisel the process was removed

There was some separation of the sacro-iliac joint, which was curetted to obtain bony ankylosis The incision was closed in the usual manner

Although it was anticipated that the pain might be more severe for a few days after the operation, such was not the case The following day the patient stated that the pain was gone Recovery was uninterrupted A plaster cast was applied for a couple of weeks after the patient got up padded and cut in such a manner as to have a tendency to straighten the spine.

Within three months the patient had returned to his usual occupation, was absolutely free from pain, and had assumed his characteristic military attitude

Case 3—*History*—S M, man aged 42 single, a stationary engineer, was sent in to my service at Wesley Memorial Hospital by a physician who had diagnosed Pott's disease The family and past history were negative

About three months before entering the hospital the patient had what he called "a stitch in the back' He rested for a couple of weeks and was then able to return to work He was working in an artificial ice plant at the time Some weeks later he put in an extra hard day's work when other men were on a holiday From then on, pain was constant and the back seemed to be curved

Physical examination was negative except for a slight curvature of the spine, marked tenderness above the sacro-iliac joint on the right side, and some limitation of motion, although there was no rigidity of the spine

The laboratory findings were negative The Roentgen ray showed a large transverse process of the fifth lumbar vertebra

The patient refused operation, and therefore was put at rest He improved sufficiently to return to work, but is not free from pain

25 East Washington Street

CAROTID TUMOR AND ANEURYSM OF THE INTERNAL CAROTID

REPORTS OF CASES

ARTHUR M SHIPLEY, M D
AND
FRANK S LYNN, M D
BALTIMORE

The common carotid has been ligated many times, and the reason for reporting these cases is not that this operation was performed, but because the two conditions for which it was ligated are rare

CASE 1—A young woman, aged 16, had, on the right side of her neck a hard lump, deeply seated, and about opposite the hyoid bone It presented just in front of the anterior margin of the sternocleidomastoid muscle It was slightly movable from side to side, but not movable in the vertical direction Its position was so deep that it seemed to be in very close relationship to the transverse processes of the cervical vertebrae The patient had suffered no inconvenience from the mass, there were no symptoms, and the reason she came for operation was the presence of a growing lump in her neck Examination showed no evidence of pressure on either the pneumogastric, hypoglossal or recurrent laryngeal nerves The lump was single, and the most careful palpation failed to reveal the presence of other masses in the neck Because it was so firm, so fixed, single, and so deeply seated, it was thought to be a sarcoma, but a diagnosis of carotid tumor was not made before operation An incision was made along the anterior margin of the sternomastoid muscle, and the lump isolated It was found to be firm in consistency, not attached to the vertebrae, and after careful dissection, it was seen that the common carotid artery tunneled the growth The internal jugular vein was firmly incorporated in the mass, but the pneumogastric nerve was not seen The growth could not be removed without the removal of the entire carotid sheath, so that the common carotid artery and the internal jugular vein were ligated above and below the growth, and the mass lifted out Almost immediately after the proximal ligature was applied, the anesthetist noticed a marked change in the character of the pulse Up until this time, the patient had been taking a quiet anesthetic with a good pulse The pulse immediately became very fast, but was still regular The operation was hastily concluded The wound was sutured without drainage, and the patient returned to bed with a pulse around 160 The pulse did not improve, continued rapid, and indeed, at times, was above 180 It was regular, however, and of fair volume This rapid pulse continued four days, but during this time, the appearance of the patient was good In spite of the rapid pulse, she had very little discomfort, no dyspnea, and no cyanosis The only treatment during this time was an ice bag over the heart, and hypodermic doses of morphin After four days of this rapid pulse, the patient was given strychnin nitrate, 1/80 grain hypodermically Within a few hours from the beginning of the administration of the strychnin, the pulse rapidly improved, and on the morning of the fifth day was 100 This patient made an otherwise uninterrupted recovery, and recently, after a lapse of nearly five years, returned to the hospital with a chronic appendicitis, for which the appendix was removed At this time, there was no evidence of recurrence

Carotid tumors are seldom reported in the literature Frazier[1] reports sixty instances collected from the literature, twenty-nine of these cases were reported by Keen and Funke,[2] and thirty-one by Callison and MacKenty[3] Of these sixty cases, five were found at necropsy Graham[4] reported that he found thirty-five cases with thirty-four complete case reports, and added two of his own, which made thirty-six complete reports Of these thirty-six, all three carotids were tied twenty-two times, the external carotid only five times The tumor was removed without ligation seven times There were evidences of vagus disturbances six times The hypoglossal nerve was cut eight times Hemiplegia occurred five times, with one death There was recurrence in four cases, and an immediate mortality of six There was one cerebral hemorrhage with recovery Two cases of bilateral carotid tumors have been reported Since the foregoing reports, five additional cases have been reported, which, with the case just narrated, bring the total up to sixty-six

Hertzger[5] gives a full report of the pathology These tumors usually have a history of slow growth They are definitely encapsulated, noninfiltrating, do not return after complete removal, and give rise to no symptoms other than deformity Later on, however, as the tumor slowly increases in size, there may be many symptoms of pressure, interference with the recurrent laryngeal, hypoglossal and pneumogastric nerves, and pressure on the larynx Pathologists report these tumors either as endothelioma, sarcoma or more correctly, perithelioma It is usually impossible to dissect them away from the carotid vessels, and if the entire tumor is not removed they usually recur In the seven cases removed without ligation, in Graham's list, four recurred These tumors vary somewhat in location The tumor is usually found at the bifurcation of the common carotid In its growth it usually involves all three carotids in its mass Sometimes, however, the growth is entirely downward from the bifurcation, and in the latter group this case belongs Complete removal is always hazardous because of the accidents which follow ligation of the common carotid, and because the tenth nerve is often so incorporated into the mass that it cannot be seen as a separate tissue, and is therefore destroyed by ligation

The carotid body or gland, sometimes called the ganglion intercaroticum, was first described by Haller in 1743 It contains many nerve fibers and some ganglion cells, which led to the supposition that it belongs to the sympathetic nervous system The body is related to the chromaffin system, and experimental work shows that its function is not important nor even essential These tumors are usually mistaken for enlarged lymph nodes or lymphosarcoma They grow very slowly and usually do not attain excessive size Several of the cases reported were the size of a hen s egg, but most of the tumors were much smaller The close relationship of the mass to the carotid artery makes its differentiation from aneurysm at times difficult There is occasionally some vasomotor disturbance, irregular flushing of the face, and moderate exophthalmos In most of the cases reported the diagnosis was not made until after removal It is a disease which usually begins in the young, but no case has been reported before the eighteenth year In the sixty cases, nineteen occurred after 40 years of age Most surgeons have advised operating on these tumors only when they are seen early in their growth Later on, when they have reached considerable size, and have become widely attached, operation becomes much more difficult, with a high immediate mortality

[5] Hertzger Treatise on Tumors

Case 2—Jan 11, 1915, a woman, aged 41, came into our care who was complaining of a mass in her throat, of gradually increasing dyspnea, very great shortness of breath on exertion some stridor, of a persistent and irritating cough, and considerable difficulty in swallowing On examination there was no external evidence of a mass but there projected into the pharynx behind the posterior pillar of the tonsil a mass whose surface was smooth, very elastic and tight on palpation and pulsating The pulsation was apparently expansile Bimanual examination with one finger in the pharynx disclosed a pulsating mass which could be compressed between the fingers so that its bulk was considerably lessened On pressure, there was a very loud bruit when the bell of the stethoscope was placed just behind the jaw and below the ear If the carotid were grasped between the thumb and finger through the sternomastoid muscle (Rouge s method) the pulsation in the mass disappeared and by pressing on the mass with the finger in the pharynx it largely disappeared The same disappearance of bruit and lessening in size of mass could be demonstrated by compressing the carotid arteries between the finger and the transverse processes of the cervical vertebrae The patient complained a great deal of a roaring sound which was very noticeable when she slept on that side This roaring was especially exaggerated when she was exercising She was seen by a number of surgeons, and various diagnoses were made The diagnoses narrowed themselves down to three aneurysm of the internal carotid tumor and cold abscess Roentgenoscopy of the cervical region revealed a very slight erosion of the transverse processes of the third and fourth cervical vertebrae There was no evidence of necrosis in any of the bodies of the vertebrae An exploratory incision was made high up in the neck, just behind the angle of the jaw, and the common carotid and its bifurcation exposed The *common* carotid was normal and the external carotid easily uncovered The internal carotid, as such could not be found Its position was occupied by an oval pulsating mass which began where the external carotid came off from the common carotid This mass was only slightly larger than the artery at first, but gradually became larger as it ascended into the neck. Compression on the common carotid was made, and with the finger in the pharynx, the pulsation disappeared, and compression caused the disappearance of the mass As soon as compression was removed from the artery, the pulsating mass immediately reappeared As consent had not been given for so serious an operative procedure as the ligation of the common carotid, the wound was closed, and the patient convalesced uneventfully The gravity of her condition was explained to her family and to herself, and ten days later, the carotid was again exposed and ligature applied This patient made an absolutely uneventful recovery None of the usual phenomena following ligature of the carotid appeared Great care was taken at the time not to injure the internal jugular vein, and especially not to injure the pneumogastric nerve There was no weakness in the opposite side of the body no paralysis of any kind, no disturbance of cerebration, and no evidence of pneumogastric injury The roaring immediately disappeared, pulsation in the mass ceased, and Jan 2, 1916, one year after ligation, the mass is still present, although slightly smaller, without pulsation, and symptoms of pressure cough, shortness of breath and difficulty in swallowing have largely disappeared

Aneurysms of the internal carotid artery are divided anatomically into intracranial and extracranial aneurysms Intracranial carotid aneurysms are reported with comparative frequency In 1,000 ligations of the common carotid, 113 were for pulsating exophthalmos Pulsating exophthalmos is usually caused by an arteriovenous aneurysm between the cavernous sinus and the internal carotid, and this condition is usually brought about by trauma to the skull

Extracranial internal carotid aneurysms are very rare Crisp mentions only two in a collection of 551 aneurysms In Matas'[6] collection of aneurysms treated after this method by American and foreign surgeons, there is not a single case of internal carotid aneurysm of the extracranial variety Herzen records it as occurring only once in his cases Monod and Vanverts in their collective cases mention one case in which restorative endo-aneurysmorrhaphy was attempted and failed because of secondary hemorrhage The most complete report is one by Bobbio,[7] who reports eighteen cases of aneurysm of the internal carotid which he had been able to find in the literature In these cases the common carotid was tied eleven times with five deaths It is fortunate that these aneurysms are rare, according to Matas, because when they do occur they are often mistaken for other conditions with fatal results Thus, in 11 extracranial aneurysms collected by Werner, only six were correctly diagnosed before treatment They are often mistaken for growths projecting into the pharynx, or for abscess near the pharynx Matas divides these aneurysms etiologically into three groups traumatic or false aneurysms, erosion aneurysms, and true arteriosclerotic aneurysms

The common carotid artery was first tied for aneurysm by Sir Astley Cooper in 1805 at Guy's Hospital, and the patient died on the nineteenth day The same surgeon repeated the operation in 1808 with success The common carotid had previously been tied for hemorrhage unsuccessfully by Mr Abernathy in 1795, and successfully by Mr Fleming in 1803 Since that time the common carotid has been tied repeatedly and the average mortality has been about 27 per cent One of the most remarkable reports showing the advantage of band over ligation was a case reported by Charles H Mayo[8] at the American Surgical Association in Washington in 1910 This patient was a woman, aged 56, who had an arteriovenous intracranial aneurysm, presumably of the internal carotid and cavernous sinus, with frightful head noises and exophthalmos She was operated on under local anesthesia, and a metal band made of a little clip of block tin was applied and tightened While the wound was being closed the patient said that the light was going out The wound was opened and the band loosened until vision returned Six months later the band was still in situ, and the patient was much improved These bands are soft enough to be compressed digitally and yet thick enough to remain closed without clips A long piece of metal with the end turned in the shape of an aneurysm needle is slipped around the artery and the handle part cut away This makes a very convenient method of handling the clip

Matas advises the following routine, although he has had no personal experience with aneurysms of the internal carotid First, the common carotid should be tied, or preferably partially obliterated by the Halsted band, and later on, completely closed If the aneurysm should relapse, extirpation might be attempted, but this would be an extremely hazardous undertaking, and hardly advisable A preferable procedure would be an obliterative endo-aneurysmorrhaphy, provided it were possible to secure the upper pole of the sac below the base of the skull In order to reach the sac, temporary resection of the lower jaw would have to be done In these cases endo-aneurysmorrhaphy should be limited to

internal suturing of the orifices of the sac and occlusion of the sac by packing The chief risk of total extirpation would be uncontrollable bleeding from the dilated internal jugular at this point, and destruction of the lower cranial nerves at their exit from the skull Most operators prefer ligation of the common carotid to ligation of the internal carotid in the treatment of these aneurysms, and in this case ligation of the internal carotid was not possible because the sac of the aneurysm began at the bifurcation The internal carotid was first ligated by Gurdon Buck of New York, reported in 1850, and in this connection it might be interesting to state what is already known to most of us, that the first ligature applied on the proximal side of an aneurysm was done by Dominique Anel, Jan 30, 1710, who ligated the brachial artery for aneurysm with recovery The most violent opposition was encountered, and as an example of the skill of detractors, they claimed, first, that it was not the brachial artery that was tied, secondly, that the ligature did not cure the aneurysm, and thirdly, that cure was by lucky chance only The old operation had been practiced in small aneurysms previous to this, which was to open the sac and ligate all bleeding points within the sac Morel attempted this operation in an aneurysm of the carotid i 1687, and lost his patient on the table from hemorrhage It was interesting to note in looking up the history of aneurysms that the femoral artery was not first tied for popliteal aneurysm by John Hunter, Dec 12, 1785, but that Desault had performed the same operation successfully January 22 of that year [9]

THE CHARCOT-MARIE-TOOTH TYPE OF PROGRESSIVE NEUROMUSCULAR ATROPHY

WITH A REPORT OF TWO CASES *

CHARLES ROSENHECK, MD
Neurologist, Hospital for Deformities and Joint Diseases
NEW YORK

Charcot and Marie,[1] in a joint contribution in 1886, first described this type of atrophy, which they considered in the nature of a dystrophy Tooth[2] in England in the same year described it independently, practically giving this affection a similar summary In 1889, however, Hoffman discovered a neurotic atrophy in the peroneal nerves, which immediately removed the affection from the category of the dystrophies and placed it in the class of primary neural degenerations Since these notable contributions, American neurologists, notably Sachs[3] and Spiller,[4] have described cases confirming the clinical syndrome of this condition The literature on the subject, although not very voluminous, is apparently divided among American, English and French authors, with an occasional case reported by Italian observers German observers, in a number of reported cases, have a tendency to include this distinct neurologic condition among the spinal atrophies, which Mashanka[5] deprecates very much, as not in accord with a true conception of the pathology of the disease

Although textbooks and monographs dwell on the rarity of the affection, Mashanka refutes the idea that it is exceptional in occurrence He believes that it is a fairly common disease, and that a great many more cases would be found if our clinical acumen was somewhat sharpened Either his contentions are correct or the disease is rare in this country

No known cause has been formulated A number of observers state that their cases followed a febrile disturbance One of my cases followed such a course Gowers[6] would class this affection among the abiotrophies, that is, a tendency for nervous tissue to suffer early decay and death

The pathology of the disease was in a chaotic state following Charcot and Marie's monograph, as it was then thought to be a dystrophy, but Hoffman, Bernhardt, Siemerling, Sainton,[7] Dejerine and Armand-Delille, in necropsy material and from a study of the recorded cases, came to the conclusion that the lesions consisted of a degeneration of the muscles, nerves and posterior columns of the spinal cord, involving the sensory and motor sides of the nerves peripherally and centrally

Although the hereditary factor is commented on strongly by most authors, isolated cases have been described in which heredity played no role in the disease My cases lacked this distinguishing feature

Occurring in families in which the hereditary factor is strong, brothers and sisters are equally affected; but if we are to include isolated cases, we find that males are five times more susceptible than females

The extreme age limits of described cases are 2 and 39 years Most cases have had their onset between the tenth and twentieth year My cases commenced at 16 and 20 years, respectively

CLINICAL COURSE

The onset is slow, although in one of my cases it was rather rapid The patient may not appreciate the atrophy until function of the limbs is interfered with Most of the cases reported in the literature mention the legs as first affected, then after a variable time, lasting from several months to several years, the upper extremities become involved It also may remain permanently localized either to the upper or lower extremities, although this is unusual My cases, of three to six years' duration, respectively, have so far selected the lower extremities When involving the upper extremities, the thenar, hypothenar and interosseus muscle bundles first show atrophy, then follow the flexors and extensors In the lower extremities, the peroneal group and antero-external part of the foot first show atrophy and diminution in muscle volume

A distinguishing feature of this atrophy is its symmetry and its distal character The proximal portions of the limbs are well preserved and show their normal contour, in striking contrast to the wasted distal portions

As a result of the atrophy, the extensors give way, thus giving us various degrees of claw hand, foot drop and equinovarus deformities The atrophy and paralysis are absolutely parallel, which condition naturally influences the gait of the patient or the use of the hands In moderate grades of wasting, there is very little interference with function of the limbs, although the gait may readily show impairment, or the hands loss of power for finer movements In extreme grades of wasting total helplessness supervenes Bony atrophy is absent and constitutes a singular feature of the cases Face, chest and trunk muscles are normal, and remain unaffected throughout the course of the disease

Fibrillary contraction constitutes a persistent feature of the affection It exists only in atrophying muscles, and stops when they are completely wasted My cases did not show this markedly, but the extreme atrophy present in both cases readily explains its absence

The reflexes in most cases reported are abolished, although Mashanka insists that they are variable, either normal, diminished, lost or increased One of my cases showed normal patellar reflexes, while the other case showed them markedly exaggerated The last condition may indicate lateral tract involvement, as particularly emphasized by Spiller Ankle clonus has been described in one case The cremasteric abdominal and upper arm reflexes have been constantly reported as normal

Electrical reactions naturally depend on the grade of atrophy In extreme atrophy, there is no response either to faradism or galvanism My cases showed an almost insignificant response in both tibialis anticus muscles with the strongest galvanic current

The sensibility is not very much disturbed subjectively Forms of cramps and paresthesias have been described, but violent and continuous pain is not a feature of the disease In contrast to these accepted observations, one of my patients developed such severe pain in one leg that she applied for admission to a hospital where a diagnosis of osteomyelitis was made and an amputation performed below the knee A small tarsal bone was subsequently removed from the other foot, but without relief to the patient in her remaining leg Objective sensibility is not altered The muscular sense is intact, and hyperesthesia is rare Vasomotor disturbances are, however, a marked feature The limbs are cold, cyanotic and erythematous, and at times show violaceous patches One of my cases showed this in striking fashion

Sphincteric troubles are absent, and evidently do not belong to this malady Organs of sense are intact and show no special disturbances The psychic state is good and the general health is remarkably well preserved The evolution of the disease is so slow and encompasses so long a period that it is quite compatible with long life and preservation of function An intercurrent illness usually closes the scene

CASE REPORTS

Case 1—E C, woman, aged 26, Russian, is the sixth child in a family of ten, seven sisters and brothers are dead of various causes The parents are living and well Two brothers are in good health There are no similar conditions in any member of the family The patient had the usual infantile disturbances, but is quite sure that she never had any acute or serious illness She is under the impression that her legs have always been thin, but she was able to use them with perfect freedom up to the age of 20, when she commenced to suffer a good deal of pain in both feet This was followed by gradually increasing weakness in both legs The patient at about this time observed the atrophy, which progressed gradually for about five years, then suddenly stopped, and for the past year has been practically stationary The pain in both feet persisted from the onset of the malady, so much, in fact, that it became quite unbearable, necessitating her admission to a hospital in this city A diagnosis of osteomyelitis (?) was made and an amputation below the knee performed on the left leg The pain persisting in the other leg, a small tarsal bone was next removed These operative procedures did not improve her condition, and at present she gets about fairly well with an artificial limb and brace

The general physical and laboratory examinations are uniformly negative The upper extremities show no abnormalities, either on inspection or with regard to function The right leg and foot below the knee joint reveal an extreme atrophy which contrasts strangely with the well preserved contour of the thigh This emphasizes the distal character of the atrophy and the preservation of the proximal part of the limb There are no objective sensory disturbances elicited The limb has a marked cyanotic hue and is covered with irregular violaceous patches Foot drop and equinovarus are present and quite evident on account of extreme shrinking of the foot In fact, it is extremely difficult, except by a liberal stretch of the imagination, to associate this small atrophic infantile foot with an adult The reflexes are present on both sides and equally exaggerated, the response in the stump of the amputated leg appearing as a grotesque and startling phenomenon Under extreme galvanic stimulation we get an insignificant response in the tibialis anticus All other muscles fail to respond with the strongest currents Muscle fibrillation is absent The patient s general health is excellent She manages to get about fairly well, and is in no way depressed in spite of her distressing condition

Case 2—J B, man, aged 19, loom fixer by occupation, had the usual diseases of childhood He has never had any acute illness except that in connection with his present affection His habits are good He does not drink, and is a moderate user of tobacco All venereal infection is denied. The family history has no bearing on the patient's present complaint, nor are there any other members of the family similarly affected The patient, as heretofore noted, was perfectly well up to the age of 16 when he had a febrile illness of unknown etiology and classification lasting three days He recovered quickly and seemed quite well for two months, when the present trouble commenced This manifested itself by an inability to walk properly There was loss of power in both legs and feet which progressively became worse for one year, then the condition remained stationary and has remained so ever since, that is, for a period of two years At no time were there any bladder, rectal or sensory disturbances

The general physical examination reveals no abnormalities, and the laboratory tests are uniformly negative The upper extremities show no involvement Examination of the legs shows an evident atrophy which has involved both feet Here we also note the distal character of the atrophy, the proximal portions of the limbs, that is, the thighs, are not involved and show a normal fleshy contour There are absolutely no sensory disturbances to be elicited, either subjectively or objectively A double foot drop is quite evident, and the gait, which is quite good, is suggestive of a 'steppage ' There is marked vasomotor disturbance, mottled areas of erythema and cyanosis being present in both limbs The patellar and Achilles reflexes are normal on both sides and there is an equal response With the strongest galvanic stimulation, a very feeble wormlike" response is elicited in the tibialis anticus of both sides, all other muscles fail to respond with the strongest faradic or galvanic stimulation The general health is excellent and the mental state has always been good

CONCLUSION

It is hoped that this study will stimulate workers in the field of neurology to recognize and isolate these neural disturbances as belonging to a distinct clinical entity and not to class them with the dystrophies with which they are often confounded[8]

247 West One Hundred and Thirty-Fifth Street

STREPTOTHRIX IN BRONCHOPNEUMONIA OF RATS SIMILAR TO THAT IN RAT-BITE FEVER

A PRELIMINARY REPORT *

RUTH TUNNICLIFF, M D
CHICAGO

Bronchopneumonia is frequent in the white rat, and occurs also in the gray rat In the course of a study of this condition, especially as it occurs in the white rat, a streptothrix was found which may be of interest in connection with rat-bite fever in man

Sixty white rats showing acute or chronic bronchopneumonia have been examined A long, fine, straight or wavy filamentous organism was observed in smear preparations or by dark field illumination in fifty-six Three lesions in which no organisms were seen were chronic The organisms are most abundant in acute lesions It is a gram-negative organism and stains fairly distinctly with carbol-gentian-violet and the Giemsa stain It is distinguished from cilia by its greater length, more pointed ends and its occasional wavy form In the dark field I have observed once or twice a slow wormlike motion, and one organism showed a corkscrew motion They are barely visible in the tissues stained with methylene blue, but are distinct in tissues impregnated with silver nitrate according to Levaditi's method Here, they appear more wavy and more fragmented than in other preparations These organisms were not observed in twenty-four normal rats

A streptothrix resembling these organisms was cultivated from twenty rats, and isolated in pure culture thirteen times Cultures from thirty-three rats remained sterile Why successful cultures were obtained from some rats and not from others is undetermined The character of the lesion does not seem to make any difference Successful cultures were more frequent in the case of sick rats and from lesions in which other bacteria were present The other organisms isolated from twenty-two rats were *Streptococcus viridans* and *pyogenes*, pneumococcus, staphylococcus, diphtheroid bacilli, anaerobic spirilla, and a profusely growing gram-negative bacillus which was probably a contamination Seven of these were isolated from cultures in which the streptothrix did not grow Successful cultures were grown on human blood agar or ascites-goat-blood-agar The various mediums for growing spirochetes were used, but no spirochetes were cultivated This streptothrix is a faculative anaerobe, growing best at 37 C (98 6 F) Slight growth appears at room temperature after several days' incubation Growth generally appears in from forty-eight to seventy-two hours as discrete, colorless or grayish pin-point colonies At first they appear dull, but later become glistening and increase slightly in size The medium is not changed The growth in the fluid of condensation and in ascites broth is white and flocculent, the medium remaining clear The growth on Loeffler's blood serum is similar to the growth on blood agar, but does not always occur There is no growth on plain and dextrose agar, ascites dextrose agar, in plain and dextrose broth or in milk

In cultures the organism is slender, branching, straight or wavy, filamentous, varying greatly in length and showing bacillus and coccuslike forms True branching is seen in young cultures, but is not especially frequent They often show spindle or irregular shaped swellings Twisted and wavy forms are more frequent on solid mediums than in ascites broth, where they appear generally as long threads or chains of bacilli They do not show a radial arrangement at the periphery of the colony They stain with ordinary stains They are gram-negative, except the swellings, and are not acid fast The organism here is nonmotile

An increase in opsonins and agglutinins for this organism has been observed in infected rats

Young healthy rats injected intraperitoneally with cultures show acute lesions in the lungs The organism has been isolated in pure culture from the heart's blood and lung

This streptothrix appears to be the same as *Streptothrix muris ratti* isolated in pure culture from the blood of patients with rat-bite fever by Schottmuller[1] and Blake,[2] and seen in the blood during the paroxysms by Tileston[3] Futaki[4] and his associates describe a motile spirochete in the skin and lymph node of two cases of rat-bite fever, but details of experiments and cultures are not available Some of the spiral forms in my Levaditi specimens closely resemble the spirochetes shown in their drawing Rats causing rat-bite fever have not been examined as far as known I have examined twenty-eight wild rats, and found one infected The lesions in the lung were the same as those observed in the white rats, and showed the same organism As the trachea of infected rats is full of mucus containing large numbers of the organisms, it is readily seen that a bite from such a rat might be infectious

Tuberculosis in Madrid—On the basis of a census of all known cases of tuberculosis in Madrid during the last four years, according to the *Siglo Medico*, Dr Codina, at a recent meeting of the Academia de Medicina, stated that of the 1,300 streets in the city, over 79 per cent had had one or more cases of tuberculosis, and over 26 per cent of the houses sheltered tuberculous inmates on a given day, and over 60 per cent had had one or more tuberculous inmates in the course of the four years That is, over three fifths of the houses of Madrid have sheltered tuberculosis in the last few years, and there are fifty-two houses that have each had from eleven to thirty-one cases He stated further that 92 69 per cent of the tuberculous have less than a peseta —20 cents—a day to live on, 7 11 per cent have from 1 to 2 pesetas, and only 0 2 per cent as much as from 2 to 4 pesetas Overcrowding and illiteracy are shown anew to be potent factors in tuberculosis, only 35 14 per cent of the tuberculous in Madrid can read

THE BACILLUS EPILEPTICUS [*]

THIRD REPORT

CHARLES A L REED, M D
CINCINNATI

In 1914 I affirmed[1] that constipation was a factor, and a very essential factor, in the causation of epilepsy I have found that constipation, always present in the patients who came to me, was caused by mechanical disturbance or distortion of the intestines, and that when these conditions of the intestines were corrected by surgical means, the patients in a large number of instances were cured without other treatment, not only of their constipation, but very often of their epilepsy

My increasing experience has confirmed the correctness of these views with respect to both the causation and the treatment of the disease I was aware from the start, however, that, while the connection between constipation as the cause and epilepsy as the effect was obvious from the history of the cases there had been given no adequate explanation or actual demonstration of the connecting link between the two conditions

While this was true, a careful study of the symptomatology, as manifested in my cases, had early convinced me that this connecting link consisted in some form of infection

Was the infection, however, restricted, as it seemed, to the intestinal canal? Were the bacteria in the intestines responsible for the evolution of toxins which, when absorbed, caused epilepsy? Were the ordinarily known organisms of the intestinal flora responsible for such toxins, or were the toxins elaborated by some special organism? Or was the offending organism, whether of the known flora or not, absorbed directly into the blood? And, after all, was the constipation which was present in all of my cases responsible for the enforced absorption, toxic or bacterial or both, into the circulation?

It was convictions such as I have expressed and questions such as I have just propounded that induced me to inaugurate investigations which have resulted in the isolation, cultivation and experimental study of an organism which, it would seem, according to the law of Koch, has a causal relation to epilepsy I feel that it is important to place findings, as far as they have gone, and conclusions, as far as they have been reached, before the profession, that they may at least serve as the basis of further investigations, especially by those with large clinical and laboratory facilities at their disposal

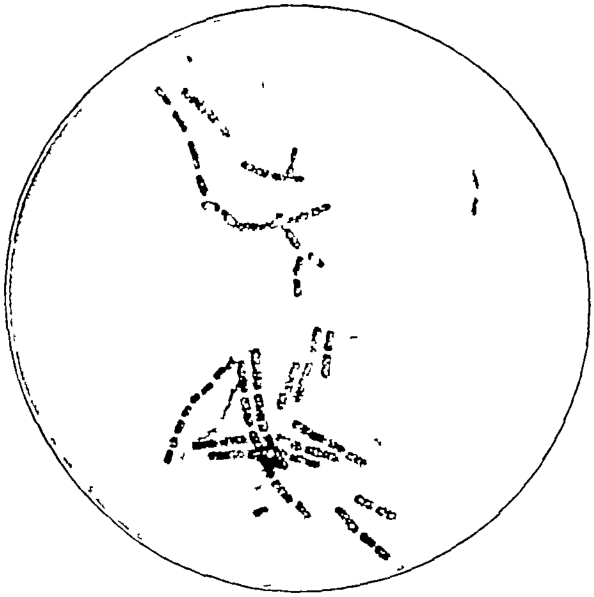

Fig 1 —Bacillus epilepticus from the blood of an epileptic patient (a) the isolated organism in the right upper quadrant is an early growth (b) the remainder of the field is occupied chiefly with mature culture from agar agar slant

METHODS OF INVESTIGATION

The investigations, begun clinically by myself, were further developed by placing Dr E P Hyatt in charge of the hematologic work of my laboratory Investigations were made in the laboratory, in the hospitals with which I am connected, and in the Nursing Home for Epileptics All patients were kept under strict observation The experimental work was done at the last named institution, where the animals were kept under constant surveillance All my patients afflicted with constipation, whether epileptics or not, on application at the office, were thoroughly examined, special attention being directed to Roentgen examination of the abdominal viscera, repeated analyses of the urine, and careful bacteriologic and other analytic examination of the blood The blood was taken from a vein in the forearm under the usual aseptic precautions, from 1 to 2 5 c c being the amount ordinarily taken This blood was examined on admission by direct smears and, later by cultures It was soon noticed that there was an organism, always the same organism, present in blood of epileptics, but that it was never present in the blood of nonepileptics It was sometimes, although rarely, found in the direct smears, but the cultures showed that it was present in a majority of cases Examination was also made of the contents of each colon that I removed The contents of each vermiform appendix were similarly examined, as were the enlarged and indurated lymphatics of the mesocecum and the mesocolon These glands were either removed with the large bowel or taken out in the course of some other operation and submitted to special examination The result was that the organism which was being found so uniformly in the blood at the time of preliminary examination was found with equal uniformity in the contents of the cecum, in that of the appendix, and also in the lymphatic glands of the same patient at the time of operation Similar investigations in nonepileptics were always negative It was concluded, therefore, that the cecum of epileptics was the very constant habitat of the organism, that the lymph channels were the highways of its transit, and that the blood was its final destination It was also noted in each of these cases that the cecum was very large, flabby and mobile, and that its dilatation with resulting attenuation of its walls was obviously the effect of stasis induced by retardative conditions further along

These observations compelled the further conclusion that mechanical conditions of the intestines, more especially of the cecum, forced the absorption of the organisms, and that such absorption would not occur in the same degree, if at all, if these retardative conditions did not exist — a conclusion which is amply confirmed by both clinical observation and postoperative results

CONCLUSION

It is hoped that this study will stimulate workers in the field of neurology to recognize and isolate these neural disturbances as belonging to a distinct clinical entity and not to class them with the dystrophies with which they are often confounded[8]

STREPTOTHRIX IN BRONCHOPNEUMONIA OF RATS SIMILAR TO THAT IN RAT-BITE FEVER

A PRELIMINARY REPORT [*]

RUTH TUNNICLIFF, M D
CHICAGO

Bronchopneumonia is frequent in the white rat, and occurs also in the gray rat In the course of a study of this condition, especially as it occurs in the white rat, a streptothrix was found which may be of interest in connection with rat-bite fever in man

Sixty white rats showing acute or chronic bronchopneumonia have been examined A long, fine, straight or wavy filamentous organism was observed in smear preparations or by dark field illumination in fifty-six Three lesions in which no organisms were seen were chronic The organisms are most abundant in acute lesions It is a gram-negative organism and stains fairly distinctly with carbol-gentian-violet and the Giemsa stain It is distinguished from cilia by its greater length, more pointed ends and its occasional wavy form In the dark field I have observed once or twice a slow wormlike motion, and one organism showed a corkscrew motion They are barely visible in the tissues stained with methylene blue, but are distinct in tissues impregnated with silver nitrate according to Levaditi's method Here, they appear more wavy and more fragmented than in other preparations These organisms were not observed in twenty-four normal rats

A streptothrix resembling these organisms was cultivated from twenty rats, and isolated in pure culture thirteen times Cultures from thirty-three rats remained sterile Why successful cultures were obtained from some rats and not from others is undetermined The character of the lesion does not seem to make any difference Successful cultures were more frequent in the case of sick rats and from lesions in which other bacteria were present The other organisms isolated from twenty-two rats were *Streptococcus viridans* and *pyogenes*, pneumococcus, staphylococcus, diphtheroid bacilli, anaerobic spirilla, and a profusely growing gram-negative bacillus which was probably a contamination Seven of these were isolated from cultures in which the streptothrix did not grow Successful cultures were grown on human blood agar or ascites-goat-blood-agar The various mediums for growing spirochetes were used, but no spirochetes were cultivated This streptothrix is a faculative anaerobe, growing best at 37 C (98 6 F) Slight growth appears at room temperature after several days' incubation Growth generally appears in from forty-eight to seventy-two hours as discrete, colorless or grayish pin-point colonies At first they appear dull, but later become glistening and increase slightly in size The medium is not changed The growth in the fluid of condensation and in ascites broth is white and flocculent, the medium remaining clear The growth on Loeffler's blood serum is similar to the growth on blood agar, but does not always occur There is no growth on plain and dextrose agar, ascites dextrose agar, in plain and dextrose broth or in milk

In cultures the organism is slender, branching, straight or wavy, filamentous, varying greatly in length and showing bacillus and coccuslike forms True branching is seen in young cultures, but is not especially frequent They often show spindle or irregular shaped swellings Twisted and wavy forms are more frequent on solid mediums than in ascites broth, where they appear generally as long threads or chains of bacilli They do not show a radial arrangement at the periphery of the colony They stain with ordinary stains They are gram-negative, except the swellings, and are not acid fast The organism here is nonmotile

An increase in opsonins and agglutinins for this organism has been observed in infected rats

Young healthy rats injected intraperitoneally with cultures show acute lesions in the lungs The organism has been isolated in pure culture from the heart's blood and lung

This streptothrix appears to be the same as *Streptothrix muris ratti* isolated in pure culture from the blood of patients with rat-bite fever by Schottmuller[1] and Blake,[2] and seen in the blood during the paroxysms by Tileston[3] Futaki[4] and his associates describe a motile spirochete in the skin and lymph node of two cases of rat-bite fever, but details of experiments and cultures are not available Some of the spiral forms in my Levaditi specimens closely resemble the spirochetes shown in their drawing Rats causing rat-bite fever have not been examined as far as known I have examined twenty-eight wild rats, and found one infected The lesions in the lung were the same as those observed in the white rats, and showed the same organism As the trachea of infected rats is full of mucus containing large numbers of the organisms, it is readily seen that a bite from such a rat might be infectious

Tuberculosis in Madrid—On the basis of a census of all known cases of tuberculosis in Madrid during the last four years, according to the *Siglo Medico*, Dr Codina, at a recent meeting of the Academia de Medicina, stated that of the 1,300 streets in the city, over 79 per cent had had one or more cases of tuberculosis, and over 26 per cent of the houses sheltered tuberculous inmates on a given day, and over 60 per cent had had one or more tuberculous inmates in the course of the four years That is, over three fifths of the houses of Madrid have sheltered tuberculosis in the last few years, and there are fifty-two houses that have each had from eleven to thirty-one cases He stated further that 92 69 per cent of the tuberculous have less than a peseta —20 cents—a day to live on, 7 11 per cent have from 1 to 2 pesetas, and only 0 2 per cent as much as from 2 to 4 pesetas Overcrowding and illiteracy are shown anew to be potent factors in tuberculosis, only 35 14 per cent of the tuberculous in Madrid can read

THE BACILLUS EPILEPTICUS*

THIRD REPORT

CHARLES A L REED, M D
CINCINNATI

In 1914 I affirmed[1] that constipation was a factor, and a very essential factor, in the causation of epilepsy I have found that constipation, always present in the patients who came to me, was caused by mechanical disturbance or distortion of the intestines, and that when these conditions of the intestines were corrected by surgical means, the patients in a large number of instances were cured without other treatment not only of their constipation, but very often of their epilepsy

My increasing experience has confirmed the correctness of these views with respect to both the causation and the treatment of the disease I was aware from the start, however, that, while the connection between constipation as the cause and epilepsy as the effect was obvious from the history of the cases there had been given no adequate explanation or actual demonstration of the connecting link between the two conditions

While this was true, a careful study of the symptomatology, as manifested in my cases, had early convinced me that this connecting link consisted in some form of infection

Was the infection, however, restricted, as it seemed, to the intestinal canal? Were the bacteria in the intestines responsible for the evolution of toxins which, when absorbed, caused epilepsy? Were the ordinarily known organisms of the intestinal flora responsible for such toxins, or were the toxins elaborated by some special organism? Or was the offending organism, whether of the known flora or not, absorbed directly into the blood? And, after all, was the constipation which was present in all of my cases responsible for the enforced absorption, toxic or bacterial or both, into the circulation?

It was convictions such as I have expressed and questions such as I have just propounded that induced me to inaugurate investigations which have resulted in the isolation, cultivation and experimental study of an organism which, it would seem, according to the law of Koch, has a causal relation to epilepsy I feel that it is important to place findings, as far as they have gone, and conclusions, as far as they have been reached, before the profession, that they may at least serve as the basis of further investigations, especially by those with large clinical and laboratory facilities at their disposal

METHODS OF INVESTIGATION

The investigations, begun clinically by myself, were further developed by placing Dr E P Hyatt in charge of the hematologic work of my laboratory Investigations were made in the laboratory, in the hospitals with which I am connected, and in the Nursing Home for Epileptics All patients were kept under strict observation The experimental work was done at the last named institution, where the animals were kept under constant surveillance All my patients afflicted with constipation, whether epileptics or not, on application at the office, were thoroughly examined, special attention being directed to Roentgen examination of the abdominal viscera repeated analyses of the urine, and careful bacteriologic and other analytic examination of the blood The blood was taken from a vein in the forearm under the usual aseptic precautions, from 1 to 2 5 c c being the amount ordinarily taken This blood was examined on admission by direct smears and, later by cultures It was soon noticed that there was an organism, always the same organism, present in blood of epileptics, but that it was never present in the blood of nonepileptics It was sometimes, although rarely, found in the direct smears, but the cultures showed that it was present in a majority of cases Examination was also made of the contents of each colon that I removed The contents of each vermiform appendix were similarly examined, as were the enlarged and indurated lymphatics of the mesocecum and the mesocolon These glands were either removed with the large bowel or taken out in the course of some other operation and submitted to special examination The result was that the organism which was being found so uniformly in the blood at the time of preliminary examination was found with equal uniformity in the contents of the cecum, in that of the appendix, and also in the lymphatic glands of the same patient at the time of operation Similar investigations in nonepileptics were always negative It was concluded, therefore, that the cecum of epileptics was the very constant habitat of the organism, that the lymph channels were the highways of its transit, and that the blood

THE BACILLUS EPILEPTICUS A SPORE-BEARING ORGANISM

A further study of the organism shows that it stains best with carbolfuchsin Methyl blue may be employed Gram's method also may be used, although it is less satisfactory than the others These stains, when positive, reveal the organism It is better, however, for reasons which shall become apparent, to stain at the same time for both the organism and for spores For this purpose, Abbott's method is usually employed which, when positive, shows the organisms red and the spores blue The result, however, so far as the direct smears are concerned, is usually negative The occasional very positive findings and the desirability of having the early and conclusive information thus afforded, however, make it important always thus to examine the fresh blood

Cultures are then made in either agar-agar or bouillon, although the organism will grow in other mediums Incubation progresses most favorably at from 37 to 40 C (98 6 to 104 F) The growth is, however, more *prompt at the latter temperature* The growths begin to manifest themselves from the second to the fifth day, and first show their pres- by marked turbidity of um A smear made oon as this turbidity me marked, shows a few organisms which may be recognized as short thick bacilli with blunt ends (Fig 1 *a*) They are actively motile The organism continues to grow, and when mature is very large, so large, indeed, that both from its size and other morphologic features, it is suggestive of a saprophyte which might easily be derived from nonsterile mediums (Fig 1 *b*) This appearance was at first so impressive that it was accepted as conclusive, and our positive cultures were abandoned as probable contaminations Our error, however, was fortunately detected when both the *organism and its spores were repeatedly detected in direct smears* The sporulation becomes marked relatively to the age of the culture It is first manifested by the appearance of a light area in the

of the o organisms This light area grows

EXPERIMENTAL STUDY OF THE ORGANISM

Experimental study of this organism has been made on rabbits by (*a*) intravenous inoculation, (*b*) intraperitoneal injection, and (*c*) administration by the alimentary canal

Intravenous inoculation was practiced by injection into a rabbit through the marginal vein of one ear A growth from an agar slant was suspended in 8 c c of physiologic salt solution Of this suspension 2 c c were injected at one time, followed at twenty-four hour intervals by from 1 to 1 5 c c similarly administered On the second day, the rabbit was observed to act peculiarly, as if confused The next day, it had a recognizable convulsion, followed by stupor After this the convulsions were more frequent These would come on suddenly The animal would fall on its side, in a state of unconsciousness As it fell, it would emit a peculiar sound described by one of the watchers as a "half cry, half choking sound" During the period of unconsciousness, which was complete, there was staring of the eyes, the head turned to one side, the muscles of the neck twitched, and there were alternate contraction and extension of all four of the legs and feet This would last from three to five minutes, after which the rabbit would lie in a stupor for from fifteen to twenty minutes Early in the course of the convulsions, the animal would appear normal in the interval between the last stupor and the next seizure On the fourth day, a direct smear revealed the organism present in the blood (Fig 3), while a hanging drop showed that it was highly motile On the fifth day, however, the seizures became coalescent and the rabbit died in status epilepticus Several repetitions of this experiment showed that the phenomena induced were essentially uniform in all cases, the variation in the time of the first onset and in intensity being relative to the magnitude of the dose and the frequency of its repetition In certain instances in which small but repeated doses were given the convulsions did not appear for fourteen days or even longer

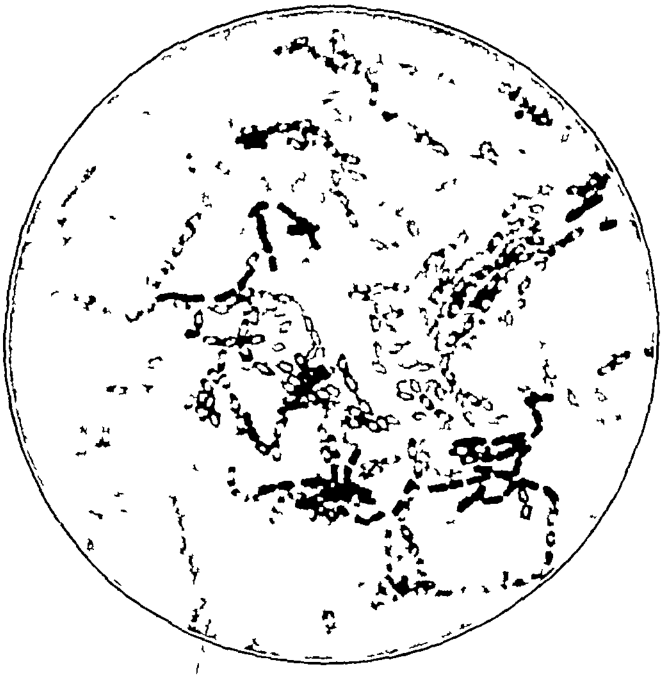

Fig 2 —Bacillus epilepticus from human subject, old culture from agar slant, showing excessive spore formation

Intraperitoneal injection was practiced to determine the toxicity of the cultures This was done by injecting the peritoneal cavity of a large rabbit with about 8 c c of the suspension similar to that previously described The animal almost at once became restless and moved about the cage constantly In an hour, it became drowsy and lay quietly down on its side, unable to move It died in this condition at the end of seven hours Necropsy revealed absence of fluid from the peritoneum, which was not in the least inflamed No organisms were found in the blood Death was therefore obviously due to simple absorption of toxins This observation was subsequently confirmed by several repetitions

Administration by the alimentary canal came about first quite accidentally A rabbit which had had some of the bacillary suspension injected into the vein of the ear was put back into the cage with a rabbit which had had no such treatment The inoculated rabbit speedily developed convulsions from which in due course it died In the meantime, the other rabbit, the one which had not been injected, developed convulsions The organism was found in the blood of this rabbit After a period of about ten days, it, too, died in continuous convulsions In accounting for the development of epilepsy in the second rabbit, it was remembered that it had licked the blood from the ear of its mate after the latter had been returned to the cage This blood was the slight reflux from the vein and, of course, brought out with it some of the organisms, which in turn were carried into the alimentary canal of the second rabbit This observation was an obvious demonstration that the organism reached the blood through the alimentary canal It was further confirmed by the fact that rabbits developed epilepsy when confined in cages which were purposely kept foul with the fecal discharges of animals in which the alimentary canal had been infected with the organism The animals which thus contracted the disease had taken food which had come in contact with the infected discharges We have had no evidence of the hematogenous infection of the intestines in animals which had been subjected only to intravenous inoculation

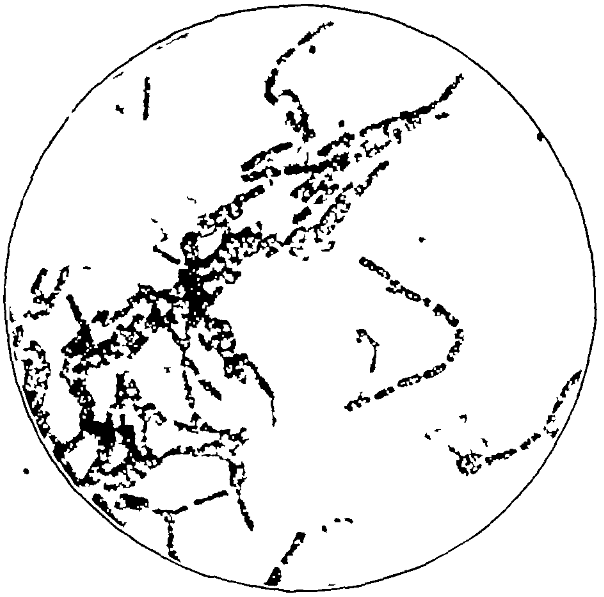

Fig 3 —Bacillus epilepticus from blood of rabbit six days after intravenous inoculation An early growth is here seen isolated in the left upper quadrant

THE BACILLUS EPILEPTICUS AND NATURAL IMMUNITY

In one particular rabbit in which a twenty-four hour growth from an agar-agar slant had been intravenously injected as before described, convulsions typically epileptic soon developed These increased in frequency and severity for the next two weeks The organism was demonstrated in the blood A little later, the seizures began to define a decrescendo in both frequency and severity into what seemed to be definite attacks of petit mal The last of these occurred just a month after the beginning of the experiment Since then the animal has had no sign of the disease Repeated examinations have failed to show the organism in the blood This spontaneous recovery has been observed in several other rabbits

This demonstrated triumph of natural immunity over the organism in rabbits throws an illuminating ray on similar results following operation in many of my cases To understand this fact, it is important, however, first to remember that in these instances of natural immunization in rabbits, the initial and only infection was effected by intravenous injection In other words, there was no focus like a large flabby and infected cecum to act as a fountain head for continued systemic invasion As a result, when the natural immunizing power of the animal had once prevailed over the invaders, the war was over There were no fresh reserves to take the place of the vanquished, and recovery resulted The probabilities are that if a preliminary focus had been established in the alimentary canal of these animals, the result would have been different As a matter of fact, all animals infected through the alimentary canal have died of epileptic seizures This principle is further illustrated in the postoperative records of certain of my cases in which, following surgical restoration of the normal fecal current and without other treatment, there was a continuance of the convulsions for some time Then the seizures began to grow lighter and fewer until there was a complete transition from the grand mal to the petit mal type Then, after a time, these ceased to occur In several of these cases, there has been no return of the seizures, their apparent cure varying from several months to as much as four years, in one case for twenty-one years

METHOD OF INVASION OF THE HUMAN SYSTEM

The facts already given would seem to be suggestive if not conclusive as to the infection of the general system through that gateway These conclusions, it would seem, are further confirmed by direct observation in many human subjects Thus it needs to be here restated that, in cases in which the blood had proved positive as to the presence of the *Bacillus epilepticus,* the same organism has been found in the cecum and in the enlarged and indurated lymphatics of the mesocecum In cases treated by appendicostomy or cecostomy, the organism is readily demonstrated in the cecal drainage until after the bowel has been successfully subjected to postoperative bactericidal treatment In cases in which the vermiform appendix has been removed at previous operation, the organism has been demonstrated in the cecum In cases in which I have removed a part of the vermiform appendix in the course of an appendicostomy, the organism has been demonstrated in the interior of the removed segment These observations, of course, are further confirmed by both the clinical phenomena and pathologic conditions uniformly found in so-called "idiopathic" epileptics[2] Thus the relationship between constipation and epilepsy would seem further to confirm the fact of a primary cecal focus under circumstances of stasis which naturally favors the more rapid multiplication of the organisms The ptotic or other retardative condition with resulting back pressure, always present in some form in these cases, mechanically enforces the absorption not only of toxins evolved by the organisms, but also of the organisms themselves These facts, associated with the additional fact that we have not so far found the organism about the tonsils or the teeth, would seem to indicate that the alimentary canal is at least the chief, if not the exclusive, atrium for the invasion of the system The final answer on this point ought, however, to be based on a much wider range of observation

---

[2] Reed, C A L Diagnostic Methods and Pathologic Constants in Idiopathic Epilepsy, The Journal A M A Jan 29 1916 p 336

COMMUNICABILITY

The mere fact that one rabbit developed epilepsy by licking epileptic germs from the ear of another rabbit, and that other rabbits developed the disease by eating food that had become contaminated by contact with fecal discharges from epileptic rabbits, at once provokes thought as to the possible communicability of the disease from one human being to another This possibility becomes the more impressive in view of two cases now under my observation Both patients are physicians One, a vigorous man of about 35, who had never been seriously ill, not only attended but assisted in the nursing of an epileptic on whom I had done an ileosigmoidostomy, and in whom there was speedy development of paralytic ileus In an effort to secure action from the bowel, the physician himself administered several enemas About five months later, this physician himself fell in an epileptic seizure, and has since had three other grand mal attacks Another physician, aged a little over 50, at this time in the hospital following operation at my hands, has had epileptic seizures of gradually increasing severity for the last twelve years He recalls that several months before his initial attack, he personally administered an enema or several of them in a case of status epilepticus His blood, cecum, vermiform appendix and retrocecal lymphatics were all positive as to *Bacillus epilepticus* at the time of operation In neither of these cases could there be anything more than a presumption based on circumstantial evidence, that, through some accidental means — possibly the hands of the victims themselves — the organism had been carried from the alimentary canal of the patient to that of the attendant The fact, however, that the records of institutions for epileptics show that a very large proportion of the cases come from the insanitary abodes of vice, poverty and other evidences of degeneracy, in short, from environments in which personal hygiene is at its lowest ebb, is suggestive of contamination rather than of inheritance It must be conceded that while the evidence so far accumulated is largely circumstantial and inconclusive, additional significance is given to it by the character of the organism itself The fact that it is a spore-bearing bacillus, and that the spores are among the most resistant yet discovered, adds to the obvious danger In a nonnutritive wet medium, they have survived under observation for quite four months without evidence of diminished vitality No observation has been made as to their survival in either a dry or moderately moist environment In view of the fact that the organism demonstrably reaches the soil through fecal discharges, and in view of the fact that its spores are highly resistant and that they can and do survive for long periods, there is strong probability that the soil may be recognized as its extracorporeal habitat This probability is increased by the fact that, morphologically, the nearest analogue of the spore-bearing bacillus of epilepsy is the equally spore-bearing bacillus of tetanus, and that the primary habitat of the latter has been demonstrated to be the soil The fact that a larger number of people have epilepsy than have tetanus is another fact suggestive of the relatively greater dissemination of the cause In view of all these facts, it may be well to take due precaution against communication until further investigation can confirm or disprove their apparent significance

PATHOGENICITY

I know no better way to outline the pathogenic effects of this organism on the human system than by quoting from my Los Angeles address of Feb 18, 1915, several months before we had succeeded in isolating the bacillus I then said [3]

> The most important conclusion that has been forced upon me by my clinical observation is that the role of constipation, as a causative factor in epilepsy, is due to the more than probable fact that the really *initial cause is to be found in a specific infection.* I am so convinced of the accuracy of this conclusion that, in the absence of actual identification of the micro-organism, not only its existence, but many of its characteristics may be predicated upon its clinical manifestations Thus it may be safely assumed that this organism, probably a bacillus, belongs to the gas-forming series Its habitat is the alimentary canal, probably originally the duodenum, but in all instances, finally, the colon It is, furthermore, obviously toxogenic From its general habitat in the intestinal mucosa, the infection may travel in either or both of two directions, namely, outward with the intestinal juice, the succus entericus, and if not promptly carried away in the alvine current, must be taken up again in the process of absorption, and in this way become an additional element in systematic contamination

In further discussion of this then hypothetic organism and its toxins, I added that they, one or both,

> *have the faculty of accumulating in the tissues and in the circulatory media* Once within the blood current, they display a selective affinity for the sensory and motor centers It is, furthermore, obvious that their effects upon these centers are relative to the size of the accumulated dose and the tolerance of the individual When the accumulation goes beyond the point of tolerance, we may have, first, a flash of unconsciousness with a minimum of muscular disturbance, or none at all (petit mal), or second, sudden and profound loss of consciousness, with violent convulsive disturbance (grand mal), or third, persistent and almost coalescent seizures of the latter variety (status epilepticus) I have demonstrated to my own satisfaction that these manifestations are identical in essence, because they are identical in causation, the variation in degree and intensity being determined by corresponding variation in the dose of the causative agent
>
> Another constitutional effect is to produce a certain amount of mental dulness, with depression amounting, in most cases, to actual narcotism of from a few minutes to several hours following explosions
>
> The infection is, furthermore, responsible for two other series of phenomena The first is local, within the intestines, and is characterized by the elaboration of gas having a characteristic and very offensive odor This gas formation may occur in some degree during the interval between attacks, but is always more marked at the time of attacks, or more properly, explosions It is then associated with more or less violent muscular disturbance of the intestines, and with the sudden stimulation of the salivary, urinary and cutaneous secretions The saliva, urine and perspiration are liable to have the same odor as the gas generated in the intestines It would seem at this time as if the patient had literally been the victim of an internal explosion, the resulting offensive and characteristic odor corresponding, for purposes of illustration, to that of burnt powder Another constitutional effect of epileptic infection is to bring the mean average temperature below the normal standard, approximately to 97 F This mean average is associated

---

[3] Reed, C A L Constipation in Relation to Various Diseases Lancet Clinic, March 13, 1915

with some vacillation, which increases until an explosion is reached, after which it again for a while remains near the mean average of the individual case

CONCLUSIONS

This review, and the facts presented, force certain conclusions which are not without practical significance

1 Epilepsy is an infection depending on a specific spore-bearing organism which it would seem that I am justified in calling *Bacillus epilepticus*[4]

2 The *Bacillus epilepticus* invades the system through the alimentary canal, its chief focus being the cecum, from which it reaches the circulation by forced absorption induced by mechanical retardation of the fecal current

3 The *Bacillus epilepticus*, by virtue of its spore-bearing characteristic, under ordinary circumstances and without appropriate treatment, has the ability in most cases to perpetuate itself indefinitely in both the cecum and the blood

4 In a certain very limited number of instances, the *Bacillus epilepticus* seems to be overcome by the natural immunity, but only where there is no focus in the intestines for the continued infection of the system — a circumstance which would seem to account for the spontaneous recovery

5 Treatment, surgical and bactericidal, to be rational and effective, must be addressed to the organism, with reference, first, to arresting its intake from the intestines, and, secondly, to its neutralization and eradication from the blood

Union Central Building

---

[4] In my article on 'Diagnostic Methods and Pathologic Constants in Idiopathic Epilepsy' (Footnote 2) I referred to this organism as the epilepticoccus ' This grew out of the fact that its morphology as shown at different stages of development was confusing as to classification Bra indicated this confusion by referring to it as a possible *coccobacille diplobacille streptobacille* ' and finally designating it the neurococcus." Hyatt has, however demonstrated that it is a bacillus. This prompts me to add that the researches chronicled in the foregoing summary had advanced to practical completion, and the organism had been isolated and identified, when a search of the Index Medicus brought to my attention the fact that the same subject had been gone over quite fourteen years previously by M Bra (Compt. rend Acad d sc, Jan 6 1902 Rev neurol 1902 p 447 Bull off Soc. méd d prat., 1902, xii, 289 Rev neurol. 1903 v 408) to whom credit for priority of investigation must be freely accorded As a surgeon, I had approached the question in a quite accidental way and from the strictly surgical standpoint. I was amazed therefore to find that so important an observation as that by Bra, although primarily published in a neurologic journal, had since been practically ignored by the neurologic profession Bra isolated the same organism injected it into rabbits, produced epileptic convulsions in them and regained the organism from the blood of the infected rabbit. The organism was found in seventy consecutive epileptics, while it was not found in twenty consecutive nonepileptics It is thus apparent that the observations and conclusions by Bra like those of my own which I have here recorded conform strictly to the law of Koch But my own investigations while completely confirming the long neglected findings of Bra have however, carried the discoveries further by showing that the organism is a bacillus that it bears spores, that it invades the system through the alimentary canal that it is highly toxogenic that it is susceptible of communication that it is in a measure controlled by both surgical and bactericidal means, and it may be and generally is self perpetuating in both the alimentary canal and the blood It would seem indeed as if Bra's great work were another example of an important discovery having been overlooked by the world just as the discovery of the law of heredity by Mendel was overlooked for many years until it was rediscovered by de Vries

G CANBY ROBINSON, MD
ST LOUIS

Auricular fibrillation is now firmly established as the disturbance of the cardiac mechanism causing the absolutely irregular pulse, a very frequent clinical phenomenon and the most usual type of cardiac irregularity observed in patients with heart disease

The nature of the fibrillary process has been interpreted in various ways, such as being the result of multiple stimulus formation in various parts of the cardiac musculature (Lewis[1]) and as a lowering of the refractory phase of the various cardiac muscle bundles (Rothberger and Winterberg[2]) The theory of Garrey[3] rests, however, on a firmer experimental basis than any other that had been advanced He considers that fibrillary contractions of the heart muscle depend on the establishment within the musculature of multiple regions of block or reduced conductivity The impulses thus blocked or delayed take abnormal and circuitous paths, and return to the same portion of the muscle after the refractory state has passed off, but while other portions are still refractory The latter portions are subsequently involved in a similar manner, and the whole tissue mass is thus thrown into a continuous incoordinated contraction, not initiated or sustained by new impulses arising from any definite location

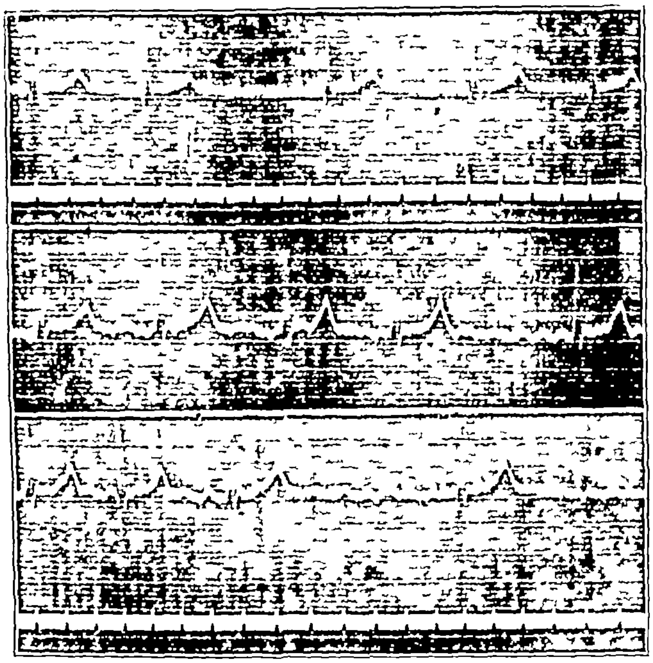

Fig 1 —Electrocardiogram obtained July 23, 1915 at 11 a m showing auricular fibrillation first and second leads

Although Garrey's observations give a clearer understanding of the nature of the fibrillary process, the essential causes which may determine its onset in the human auricles remain obscure Gossage and Hicks[4] have discussed the question of causation of auricular fibrillation, and point out two possibilities The first possibility considers that the fibrillation is due to some morbid condition of the muscle fibers, the actual ultimate stimulus which starts it being some sudden strain or the cumulative effect of prolonged overwork, as might be imagined to occur in valvular disease The second possibility considers that the fibrillation is due to some extrinsic stimulus (for example, an altered chemical constitution of the blood) which, while more likely to influence an already diseased organ, might yet, if sufficiently strong, cause fibrillation in a heart that themselves These facts, associated with the additional fact that we have not so far found the organism about the tonsils or the teeth, would seem to indicate that the alimentary canal is at least the chief, if not the exclusive, atrium for the invasion of the system The final answer on this point ought, however, to be based on a much wider range of observation

COMMUNICABILITY

The mere fact that one rabbit developed epilepsy by licking epileptic germs from the ear of another rabbit, and that other rabbits developed the disease by eating food that had become contaminated by contact with fecal discharges from epileptic rabbits, at once provokes thought as to the possible communicability of the disease from one human being to another This possibility becomes the more impressive in view of two cases now under my observation. Both patients are physicians One, a vigorous man of about 35, who had never been seriously ill, not only attended but assisted in the nursing of an epileptic on whom I had done an ileosigmoidostomy, and in whom there was speedy development of paralytic ileus In an effort to secure action from the bowel, the physician himself administered several enemas About five months later, this physician himself fell in an epileptic seizure, and has since had three other grand mal attacks Another physician, aged a little over 50, at this time in the hospital following operation at my hands, has had epileptic seizures of gradually increasing severity for the last twelve years He recalls that several months before his initial attack, he personally administered an enema or several of them in a case of status epilepticus His blood, cecum, vermiform appendix and retrocecal lymphatics were all positive as to *Bacillus epilepticus* at the time of operation In neither of these cases could there be anything more than a presumption based on circumstantial evidence, that, through some accidental means — possibly the hands of the victims themselves — the organism had been carried from the alimentary canal of the patient to that of the attendant The fact, however, that the records of institutions for epileptics show that a very large proportion of the cases come from the insanitary abodes of vice, poverty and other evidences of degeneracy, in short, from environments in which personal hygiene is at its lowest ebb, is suggestive of contamination rather than of inheritance It must be conceded that while the evidence so far accumulated is largely circumstantial and inconclusive, additional significance is given to it by the character of the organism itself The fact that it is a spore-bearing bacillus, and that the spores are among the most resistant yet discovered, adds to the obvious danger In a nonnutritive wet medium, they have survived under observation for quite four months without evidence of diminished vitality No observation has been made as to their survival in either a dry or moderately moist environment In view of the fact that the organism demonstrably reaches the soil through fecal discharges, and in view of the fact that its spores are highly resistant and that they can and do survive for long periods, there is strong probability that the soil may be recognized as its extracorporeal habitat This probability is increased by the fact that, morphologically, the nearest analogue of the spore-bearing bacillus of epilepsy is the equally spore-bearing bacillus of tetanus, and that the primary habitat of the latter has been demonstrated to be the soil The fact that a larger number of people have epilepsy than have tetanus is another fact suggestive of the relatively greater dissemination of the cause In view of all these facts, it may be well to take due precaution against communication until further investigation can confirm or disprove their apparent significance

PATHOGENICITY

I know no better way to outline the pathogenic effects of this organism on the human system than by quoting from my Los Angeles address of Feb 18, 1915, several months before we had succeeded in isolating the bacillus I then said [3]

> The most important conclusion that has been forced upon me by my clinical observation is that the role of constipation, as a causative factor in epilepsy, is due to the more than probable fact that the really initial cause is to be found in a specific infection. I am so convinced of the accuracy of this conclusion that, in the absence of actual identification of the micro-organism, not only its existence, but many of its characteristics may be predicated upon its clinical manifestations Thus it may be safely assumed that this organism, probably a bacillus, belongs to the gas-forming series Its habitat is the alimentary canal, probably originally the duodenum, but in all instances, finally, the colon It is, furthermore, obviously toxogenic From its general habitat in the intestinal mucosa, the infection may travel in either or both of two directions, namely, outward with the intestinal juice, the succus entericus, and if not promptly carried away in the alvine current, must be taken up again in the process of absorption, and in this way become an additional element in systematic contamination

In further discussion of this then hypothetic organism and its toxins, I added that they, one or both,

> have the faculty of accumulating in the tissues and in the circulatory media Once within the blood current, they display a selective affinity for the sensory and motor centers It is, furthermore, obvious that their effects upon these centers are relative to the size of the accumulated dose and the tolerance of the individual When the accumulation goes beyond the point of tolerance, we may have, first, a flash of unconsciousness with a minimum of muscular disturbance, or none at all (petit mal), or second, sudden and profound loss of consciousness, with violent convulsive disturbance (grand mal), or third, persistent and almost coalescent seizures of the latter variety (status epilepticus) I have demonstrated to my own satisfaction that these manifestations are identical in essence, because they are identical in causation, the variation in degree and intensity being determined by corresponding variation in the dose of the causative agent
>
> Another constitutional effect is to produce a certain amount of mental dulness, with depression amounting, in most cases, to actual narcotism of from a few minutes to several hours following explosions
>
> The infection is, furthermore, responsible for two other series of phenomena The first is local, within the intestines, and is characterized by the elaboration of gas having a characteristic and very offensive odor This gas formation may occur in some degree during the interval between attacks, but is always more marked at the time of attacks, or more properly, explosions It is then associated with more or less violent muscular disturbance of the intestines, and with the sudden stimulation of the salivary, urinary and cutaneous secretions The saliva, urine and perspiration are liable to have the same odor as the gas generated in the intestines It would seem at this time as if the patient had literally been the victim of an internal explosion, the resulting offensive and characteristic odor corresponding, for purposes of illustration, to that of burnt powder Another constitutional effect of epileptic infection is to bring the mean average temperature below the normal standard, approximately to 97 F This mean average is associated

GRANULOMA PYOGENICUM OF THE LIP

RICHARD L SUTTON, M D
KANSAS CITY, MO

Despite the comparative frequency with which granuloma pyogenicum occurs, the condition has attracted very little attention in this country The disorder was first described under the title of "botryomycosis hominis" in 1897, by Poncet and Dor,[1] who believed the disease to be analogous to botryomycosis of horses (Rivolti[2]) Two years later Sabrazes and Laubie[3] demonstrated the identity of the so-called "botryomycosis" with the common *Staphylococcus aureus,* and their conclusions were verified by Bodin[4] in 1902 Since then French writers have referred to the condition as "pseudo-botryomycosis hominis" or "granulome pedicule" (Lenormant)[5] In 1904, Hartzell[6] reported a series of four cases of the disease from America, and suggested for it the very apt designation of "granuloma pyogenicum," a title which has received general approval and acceptance Kuttner[7] has proposed the name of "granuloma telangiectodes," but it is hardly probable that this appellation will be widely adopted, as it is neither so euphonious nor so appropriate as the one introduced by Hartzell Wile[8] has recently made an exhaustive study of the condition He concludes that "the entire group of so-called pseudo-botryomycosis hominis, granuloma simplex, granuloma telangiectodes and granuloma pyogenicum may be grouped in one class, and may be regarded as ordinary granulation tissue, appearing, for as yet undetermined reasons, in the unusual form of a tumor The etiologic factor is not a fungus, but probably the *Staphylococcus aureus,* perhaps in an unfavorable soil or in an attenuated form The histologic changes are essentially the same in all forms, minor differences being simply in degree of vascularity and inflammation Although never malignant, the growths tend to recur, unless cauterization of the base is practiced ")

The little tumors are commonly, but not invariably, situated on those parts which are most frequently subjected *to trauma, consequently* the hands and feet are favorite sites for their development (Brocq[9])

Cases involving the lip have been reported by Poncet,[1] Savariaud and Deguy,[10] Delore,[11] Legroux,[12] Picque,[13] Le Berre,[14] Terrier,[15] Balzer and Alquier[16] and Noury[17] in France, and Gilchrist[18] in America During the past year I have observed three instances in which this region was affected

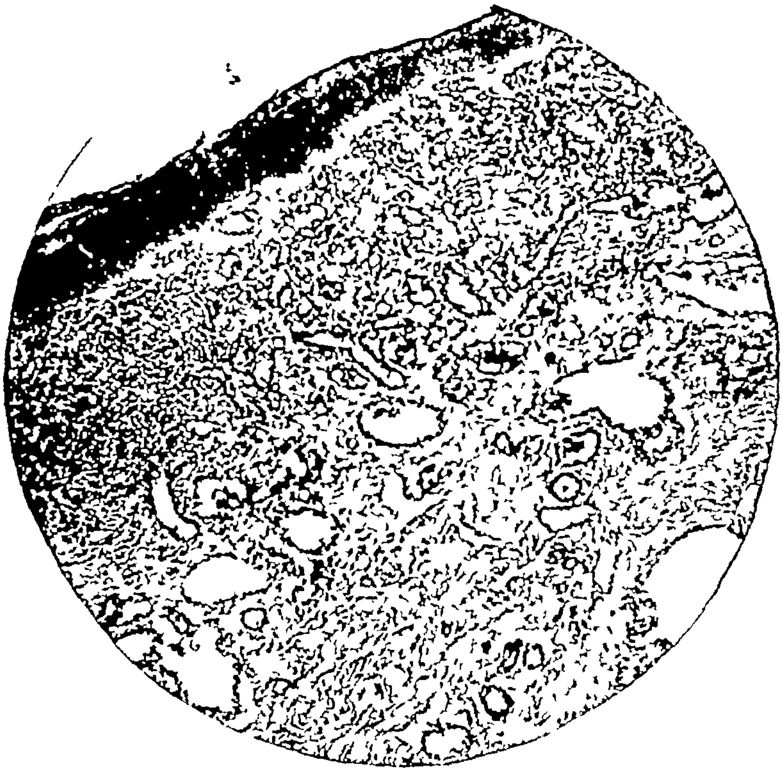

Fig 1 (Case 1)—Granuloma pyogenicum of the lip, near base of growth Composition of epithelial covering is shown, together with character of connective tissue stroma and size and distribution of blood vessels and cavities An area of leukocytic infiltration is shown at the left hand margin (Leitz, No 4 ocular, No 3 objective, 18 cm extension)

REPORT OF CASES

Case 1—In a housewife, aged 25, referred to me by Dr M A Hanna of Kansas City, the lesion had developed on a small, raw surface left by a fever blister near the mucocutaneous juncture on the lower lip, at a point not far from the median line, and had existed eight months At first it appeared only as a small red papule, but it gradually increased in size until, at the end of three months, it was as large as a grain of wheat The surface was smooth, red and shiny, and the lesion bled profusely when handled The base was not indurated There was no pain at any time On examination, the patient was found to be a slender but well nourished woman, with brown hair and eyes, and a smooth, soft skin With the exception of a few acne lesions on the face and chest, the integument on parts other than the lip was normal The growth was a small, pedunculated tumor, about the size and shape of a cherry stone dark red, with a shiny, glazed epithelial covering Histologically it consisted of a mass of *new and old connective tissue,* permeated by numerous large, thin-walled vessels, and enclosed in a thin epithelial capsule which consisted of four or five layers of slightly altered prickle cells, an attenuated stratum granulosum, and a loosely adherent stratum corneum The papillary bodies near the base of the pedicle were hypertrophied, but within the growth they had totally disappeared, leaving the under surface of the limiting membrane smooth and unmarked The dense connective tissue in the center of the tumor was traversed by innumerable blood vessels of various sizes, running in all directions Numerous leukocytes, lymphocytes, and plasma cells were observed along the courses of the capillaries and scattered about in the stroma Only a few groups of cocci were found, and these were located near the base of the growth

Case 2—In a man, aged 25, a law student, referred to me by Dr Jabez N Jackson, the lesion had developed from a tiny razor cut, on the left side of the lower lip, and had been present four months It had been removed twice during this period, once by means of a ligature and again with scissors, but had promptly recurred each time As in Case 1, there was profuse hemorrhage on even slight manipulation of the tumor, and the patient was greatly worried, suspecting malignancy

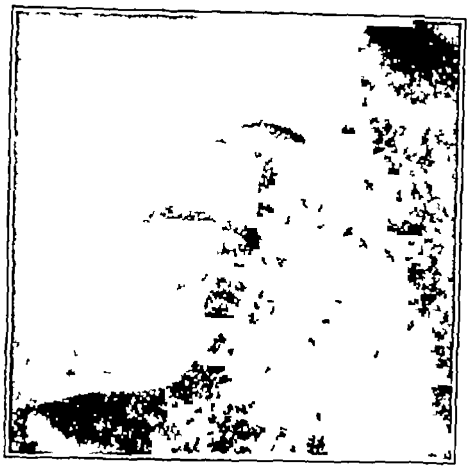

Fig 2 (Case 1) —Granuloma pyogenicum of the lip, of eight months' duration

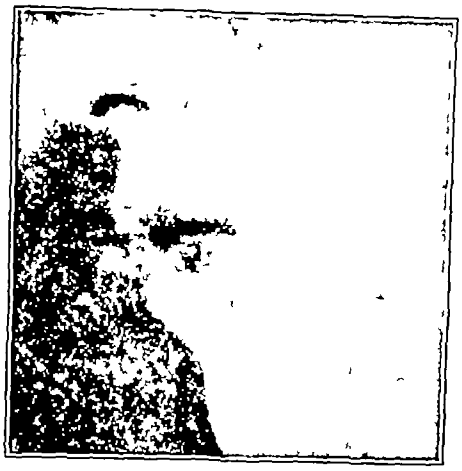

Fig 3 (Case 2) —Granuloma pyogenicum of the lip, of five months' duration

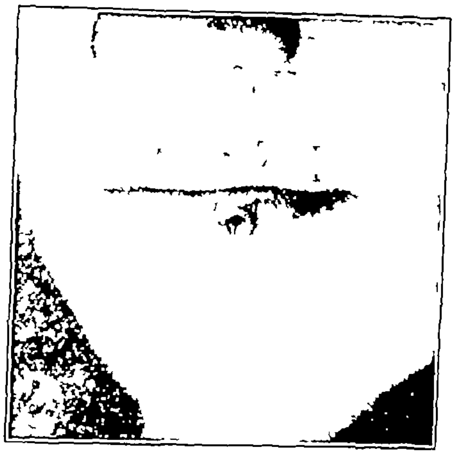

Fig 4 (Case 3) —Granuloma pyogenicum of the lip, of seven months' duration

Case 3—This occurred in a housewife, aged 30, referred to me by Dr W Connelly Anderson of Kansas City, Mo The lesion which was a trifle larger than the head of an ordinary pin, had developed on the site of a fever blister, and had been present seven months Superficial cauterization with silver nitrate had aggravated the condition instead of benefiting it The tumor was soft and compressible, but bled on very slight provocation The patient said that the growth temporarily increased in size immediately preceding each menstrual period

TREATMENT

In all three instances excision, under novocain anesthesia, was practiced, the raw bases sponged dry, and then thoroughly and deeply frozen by means of a hard, pointed stick of Pusey's carbon dioxid snow While this agent is not a direct antiseptic, it is probable that the arterial hyperemia which follows its use is of assistance in combating infection, and the cauterizing action of the refrigerant leaves little to be desired in the treatment of growths of this character

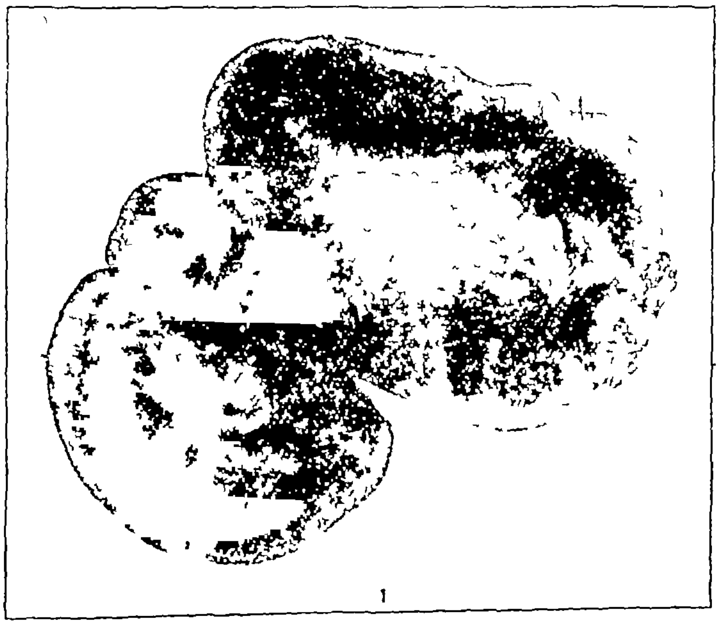
HYDROSALPINX WITH TWISTED PEDICLE

H J WHITACRE, BS, MD

TACOMA, WASH

I believe that hydrosalpinx with twisted pedicle has not been given the attention as a definite surgical condition which is its due Ovarian cyst with twisted pedicle receives definite consideration in every differential diagnosis in which an acute pelvic lesion with tumor arises, yet hydrosalpinx with twisted pedicle is not mentioned in some of our textbooks of differential diagnosis, and others merely mention the possibility I have encountered two such cases within a brief space of time, and feel that they should be reported Both of these patients suffered the sudden, severe seizure which is characteristic of the same accident with ovarian cyst, and in each instance a complete twist of the broad ligament was found beneath a tremendously dilated fallopian tube The tumor mass was in each instance from blue to black, and the fallopian tube contained blood The lesion found in each was a hematosalpinx, and should be so styled, yet the foregoing caption is given since a study of the history of these cases, together with a careful study of the pathologic material, leaves little doubt as to the fact that these patients suffered primarily from hydrosalpinx of very considerable size, that the enlarged tube became twisted on its broad ligament pedicle in a manner quite analogous to the ovarian cyst twist, and that the effusion of blood into the tube was secondary and was the direct result of the circulatory disturbance caused by the twist in the broad ligament



Hydrosalpinx with twisted pedicle Tumor mass in Case 1 (Whitacre)

These cases recall to my mind a number of earlier cases in which a large, freely movable hydrosalpinx was encountered, and in which this twist might easily have occurred The infrequency of the accident herewith reported will probably be explained by the fact that hydrosalpinx is usually accompanied by more or less extensive adhesions within the pelvis, and that these adhesions prevent free mobility of the cystlike tube

Case 1—Miss A, aged 23, was referred to me in April 1915 by Dr Rich of Roy, Wash She had suffered from gonorrhea two years previously, had borne a child one year previously, and had suffered to a moderate degree from pelvic discomfort and pain Three days previous to her admission to the hospital she had been seized with sudden severe pain in the right iliac region, vomited and felt very ill A rapidly increasing pulse and temperature rigidity of the right rectus, constant pain, and the discovery of a tumor mass in the right side led to the conclusion that the patient suffered from acute appendicitis with abscess formation My own examination of the patient introduced an element of doubt regarding this diagnosis, since bimanual examination revealed a large rounded, movable mass which occupied the entire right half of the pelvis and extended beyond the median line The mass was not extremely sensitive, seemed just beneath the abdominal wall and was not particularly marked in the culdesac Ovarian cyst with twisted pedicle and ectopic pregnancy were not fully excluded and an exploratory incision was made in the midline There was much free blood-colored serum in the free peritoneal cavity and a dark blue or black cystlike tumor presented A complete turn was demonstrable in the pedicle of this freely movable tumor and it became at once evident that the tumor mass was made up of a tremendously enlarged left tube and a huge ovary, and that the twisted pedicle was the broad ligament The tumor mass which is shown in the accompanying illustration measured 7 inches in length and 5 inches in diameter The recovery of the patient was uneventful

Case 2—Mrs B, aged 45 married multipara, was seen in consultation with Dr P B Swearingen of Tacoma It is unnecessary to give the history of this patient in detail except to state that the early symptoms of severe abdominal pain, vomiting, distention, and the failure to move the bowels by enemas, were suggestive of intestinal obstruction, and that our subsequent study of the case led us to operate on her for ovarian cyst with twisted pedicle The lesion was precisely the same as that found in Case 1 except that the bluish-black mass was not quite so large This patient also made an uneventful recovery

I feel that even though these cases present a symptomatology and call for an operative management which differs in no way from ovarian cyst with twisted pedicle, they should have a definite pathologic classification

---

The Reporting of Venereal Diseases—A recent *Bulletin* of the health department of New York City reviews the situation with reference to the reporting of venereal diseases, and states that there has been a perceptible falling off in the number of cases reported during 1915 It is believed that this is largely due to a falling off in the number of cases reported by hospitals and institutions Whereas during 1914 a total of 14 484 were reported from this source, during the year 1915 the figure dropped to 10,065, a decrease of more than 4,000 cases The percentage of positive cases reported through the department's laboratory during 1915 also shows a diminution of 5 per cent over that of 1914 The records show that the number of cases referred by the profession to the venereal diagnostic clinics is steadily increasing despite the larger number of physicians who are making the tests themselves It seems that as in the past physicians have refrained from reporting their cases in private practice, only 103 cases of venereal disease having been reported through this source for the entire year of 1915 The report points out, in this connection, that every safeguard is provided to protect the secrecy of such reports, and that it is not obligatory to report the cases by name, the initials alone being sufficient

THE MICROSCOPIC EXAMINATION OF FINGER NAIL DEPOSITS

SIGNIFICANCE IN FORENSIC MEDICINE AND IN PUBLIC AND PERSONAL HYGIENE

ALBERT SCHNEIDER, PhD, MD
SAN FRANCISCO

The microscopic examination of the deposits under the finger nails promises to be of importance in forensic medicine and also in certain phases of public sanitation and personal hygiene This form of examination has been known for some time, and has been practically applied in a number of criminal cases both in this country and in Europe, but so far it has not been adopted as an officially recognized routine in the examination of criminals or those suspected or accused of having committed certain crimes The possibilities of this procedure became apparent to me over twenty-five years ago when incidentally examining the scrapings from my own finger nails and those of my laboratory assistants The number and variety of substances found was astonishing Since that time the microscopic examination of finger nail deposits has been made a laboratory exercise for students in connection with the study of fiber and of body cells and bacteria

This particular exercise was at first sandwiched in as a diversion rather than a part of the regular course Each student of a class of forty or fifty was requested to mount the scrapings from the nails of the second and third fingers of the right hand (in case of right handed persons) on a slide in a drop of water and to examine this carefully under the high power (450 diameters) of the compound microscope The findings proved interesting and not infrequently astonishing to the student The most important part of this laboratory exercise was the interpretation of the findings The findings gave evidence of the routine labors engaged in for periods of from one to eight days previous, and of personal habits, of the kind and quality of clothing worn, of business occupations, etc

It was found that there was a very notable difference in the contents of the deposits of the nails of the right and the left hands, and also in the deposits of the nails of fingers and thumb of the same hand Numerous examinations proved that the ordinary methods of cleaning the hands by means of soap, hot water and clean towel, inclusive of the usual nail trimming and polishing, as observed by persons of clean and sanitary habits, does not materially alter the microscopic findings, in other words, the usual hand toilet operations do not clean the hands and certainly do not cleanse the inner surface of the free ends of the finger nails Even the vigorous use of the nail brush with soap and hot water does not result in a removal of all the deposits Of far greater influence is the habitual close trimming of the finger nails as observed by some persons If the nails are regularly trimmed very close, to the point of nearly causing bleeding, very little deposit of any kind will find lodgment This practice is rare, however, and may be considered the exception to the rule

The bacteriologic findings of the finger nail deposits are also very interesting The streptococcus group apparently predominates in most persons, rather than the staphylococcus or the colon bacillus group, as one might reasonably expect The organisms found in the rather limited number of cases (143) examined predominate in the following order

1. Streptococcus group, the acid fast varieties predominating.
2. Staphylococcus group.
3. *Bacillus coli* group, almost invariably present.
4. Bacilli, cocci and spirillae probably derived from mouth, soil, food, water, body surface, nose, eyes, sewage, dust, dirt, etc.
5. Occasional yeast cells, spores and filaments of higher fungi.
6. Larvae of vermes, occasional amebas, diatoms, algae, etc.

From the medicolegal standpoint, the examination of nail deposits will prove of greatest value in those criminal acts in which great violence is employed, as in murder, physical encounters of all kinds, and rape or attempted rape. In such cases it would be desirable to examine the nail deposits of both the accused and the accuser, for as is known, persons are not infrequently falsely accused, and particularly is this true in charges of rape or attempted rape. For example, scratches and other skin abrasions on hands and face of the accused should reveal skin epithelium, dermal fragments, blood corpuscles and possibly hair fragments of the accused in the nail deposits of the victim. If such findings proved wholly negative, especially in the absence of marked injury to the genitalia of the accuser, it would point to either false accusation or perhaps voluntary submission. Valuable evidence may also be obtained in other criminal acts. A husband was accused of having induced his wife to submit to the performance of criminal abortion and to have disposed of the fetus. The examination of the husband's finger nail deposits revealed a number of frustules of fresh water diatoms and a few filaments of oscillaria which led to the suspicion that he had buried the fetus in some marshy soil. Careful search along the marshy edge of a nearby stream revealed no newly made grave, but a slightly scooped out depression in the edge of the stream itself proved to be the burial place, and on digging disclosed the nearly full term fetus.

Efficiency in the line of investigation suggested above depends on long experience in micro-analytic work and on a wide range of microscopic study of all kinds of substances, animal, vegetable and mineral. The time required to qualify as expert in this line would vary, depending on personal differences, but in all probability the requisite experience, in addition to the necessary educational preparation, such as medical course, university course, special college course, etc., could not be attained in less than ten years of constant application.

In medicolegal cases the nail deposits should be taken in the presence of the chief of police, if possible. In some cases it may be desirable and necessary to take the nail deposits on the spot, and the analyst must therefore be vested with the necessary police authority to do this, and he must furthermore be authorized to call to his assistance any police officer that may be available. The deposits should be examined immediately, if possible, in a laboratory supplied with the necessary apparatus and chemical reagents. There must be on hand suitable report blanks on which the findings are to be recorded in ink or by means of an indelible pencil.

After the examination is completed, the findings should be summarized and interpreted. The greatest care must be observed in the interpretation of the results of the examination. The analyst must qualify as an expert and he must be free from all bias and in no case must he allow prejudice to influence him in any manner whatsoever. When called on to give an opinion, he must be able to speak as one who knows, and he must cast aside all prejudice both as to the scientific and moral principles which may be involved and as to the persons or personalities implicated. At no time must he allow himself to be in any way influenced by the opinions expressed by any member or members of the police force with whom he is of necessity associated.

Thus far the medical profession has given little attention to the part played by the finger nail deposits in the transmission of infections. That there is danger in the handshake is generally recognized and admitted by the laity as well as the medical fraternity, but so far there is no effort made to do away with this ancient custom. There are certain persons who refuse to shake hands or who do so under mental protest. The Chinese do not shake hands with each other, but perform this ceremony by shaking hands with themselves.

The chief source of danger in the handshake is in the deposits under the finger nails rather than in the hand and fingers. The more important infections traceable to the finger nail deposits may be divided into two groups as follows:

1. Autoinfections.—There is no doubt that many skin diseases are traceable to scratching. Of such nail borne autoinfections we may mention lupus, acne, boils and carbuncles, and septicemia. In this manner infections are carried to nose, to eyes, to ears and to mouth and throat. Skin infections are transferred from one part of the body to another by the scratching and skin picking habit or by constantly "digging" or "picking" at a sore spot, and as a result some persons are never quite free from boils and acneic eruptions, particularly persons with low opsonic indexes to the causative infections. Infants and young children are constantly picking up infections with their finger nails and transferring these to the mouth, nose, throat and eyes. Nail biters very frequently infect themselves through the materials under the nails. Children and some women have the habit of bringing the fingers to the mouth, thus favoring the transfer of infecting material from finger nails to mouth.

2. Heteroinfections.—In many cases the infection is traceable to the finger nail deposits of others, as by handshaking, stroking or caressing the head or face, etc. There is the case of the husband whose neck on the left side was never long free from one or more small pimples or boils traceable to his wife's habit of playfully pinching his neck. He ascribed the trouble to starched collars, but several changes in the laundry brought no relief. During the prolonged absence of his wife on a visit with relatives, the trouble disappeared entirely to reappear again on her return with a renewal of the playful habits.

It certainly requires no lengthy argumentation to prove that there is danger in the finger nail deposits. Most valuable information could no doubt be obtained through a careful microscopic and bacteriologic investigation of the nail deposits of the different classes and races of people. Such information would be of inestimable value to physicians, to sanitarians and to the public in general. Furthermore, the occasional if not routine examination of finger nail deposits of patients would frequently give the attending physician valuable information regarding the source of the causative infections and personal habits which might have bearing on the disease

This brief outline of a very important as well as interesting subject will, it is hoped, serve as a stimulus to others for making additional observations and investigations along the lines indicated

THE PSEUDOREACTION IN THE SCHICK TEST AND ITS CONTROL *

ABRAHAM ZINGHER, M D
NEW YORK

The pseudoreaction in the Schick test is caused, not by the soluble diphtheria toxin, but by the protein substance of the diphtheria bacillus which is present in the solution used for the test The reaction may be obtained in individuals who have enough natural antitoxin to render them immune to diphtheria It is important, therefore, to control these pseudoreactions, which are quite frequent in the adult, especially women (from 20 to 30 per cent), but relatively rare in children These control tests may be made after the reaction with the regular Schick test has developed, or, especially in the adult, the two tests may be made simultaneously, one on each forearm and the clinical course of the reactions thus compared

For the Schick test, the bureau of laboratories of the health department is supplying an outfit which contains carefully measured amounts of undiluted diphtheria toxin This outfit, as previously described by me,[1] consists of a capillary tube which contains a little over one minimum lethal dose of a ripened diphtheria toxin, a small rubber bulb for expelling the toxin, and a 10 c c bottle of normal saline solution for diluting the toxin Every 0 2 c c of the dilution represents one fiftieth minimum lethal dose, the amount used in the Schick test

The outfit for controlling the positive, pseudo and combined reactions is similar to the Schick test outfit, but the toxin in the capillary tube has been heated to 75 C (167 F) for five minutes Heating the toxin at this temperature destroys the soluble diphtheria toxin, but does not appreciably affect the protein of the diphtheria bacillus

We made an attempt during the past two and one-half years, during which time the work with the Schick test has been carried on by us at the Willard Parker Hospital and various other institutions, to control as many of the pseudo and combined reactions as possible Convinced of the fact that the pseudoreaction was a local anaphylactic response to the protein of the diphtheria bacillus, we at first used a solution containing the autolyzed substance of the Klebs-Loeffler bacillus This autolysate consisted of a forty-eight hour agar growth of the diphtheria bacillus (No 8 Park & Williams) which was suspended in salt solution in the proportion of 10 c c of saline to a Blake bottle culture The bacterial suspension was washed four times with saline solution, made up to its original volume with distilled water, then shaken for two hours, killed at 57 C (134 6 F) for forty-five minutes and allowed to autolyze in the thermostat over night The solution was then passed through a Berkefeld filter, and the filtrate considered as a concentrated autolysate Ten c c of the autolysate, representing the growth of one Blake bottle, injected subcutaneously into a guinea-pig, did not show any evidence of soluble toxin When the bacterial suspension was injected before its passage through a Berkefeld filter, a small knoblike induration developed, which soon disappeared For use in the control of the Schick test in human beings, the concentrated autolysate was diluted 1 20 with salt solution, and 0 2 c c injected intradermally Typical false reactions were obtained in the pseudo and combined Schick cases, but none in the negative or positive cases By using a more concentrated solution of the autolysate, faint reactions could be obtained even in individuals who gave a negative Schick reaction

The difficulty of estimating the amount of bacillus protein in the diphtheria toxin broth used in the Schick test which would serve as a guide in making a proper dilution of the autolysate, prompted us finally to abandon the autolysate as a suitable control, and use either a toxin which had been slightly overneutralized with antitoxin, or a heated toxin in a dilution similar to that used in the Schick test In the overneutralized toxin (2 units of antitoxin to each L + dose of toxin) we had added however, another element, the antitoxin This, though in extreme dilution (1 part to a million as finally injected), might yet be objected to as a possible additional source of error We finally used the heated toxin as representing probably the most accurate way for obtaining a proper control test A dilution of the protein substance of the diphtheria bacillus is thus obtained which is exactly similar to that in the solution used for the Schick test The capillary tubes in the outfits represent simply a convenient and accurate way for heating the carefully measured amounts of diphtheria toxin

The Research Laboratory of the New York City Health Department is now supplying these outfits They will remain good for use for a long time, since there is no danger of deterioration of an unstable toxin

The following are the directions accompanying the outfits

DIRECTIONS FOR USING HEATED DIPHTHERIA TOXIN IN CONTROLLING THE SCHICK REACTION

Break off one end of the capillary tube push the broken end carefully through the neck of the rubber bulb until it punctures the diaphragm within, and enters the cavity of the bulb, then break off the other end of the tube Hold the bulb between the thumb and middle finger, place the index finger over the opening in the larger end of the bulb and expel the toxin into the saline Rinse out the capillary tube by drawing up saline several times then cork the bottle and shake the diluted toxin Inject 0.2 c c *intracutaneously* on the flexor surface of the forearm or arm Observe the reaction at the site of injection at the end of twenty-four, forty-eight, seventy-two and ninety-six hours, and compare with the original Schick reaction

The capillary tube in this outfit contains the culture fluid similar to that used in the Schick test, but heated to 75 C for five minutes The heating destroys the diphtheria toxin, which is the active agent in the positive Schick reaction, but does not affect the protein substance of the diphtheria bacillus, which produces the pseudoreaction

In an individual who gave a *positive* reaction only, the control test with the heated toxin will be negative. In one who gave a *pseudoreaction,* the control reaction will be of about the same size and appearance, and pass through the same clinical course as the original reaction, e. g., the two reactions showing a similar central area of redness of varying size, surrounded by a secondary areola which shades off into the surrounding skin. Both reactions begin to appear in about six to eighteen hours, reach their height in twenty-four to thirty-six hours and disappear in three to four days, leaving a poorly defined area of pigmentation and generally no scaling.

---

* From the Research Laboratory of the Department of Health City of New York

[1] Zingher Abraham A Simple Outfit for the Distribution of Toxin for the Schick Test The Journal A M A July 24 1915 p 329

In an individual who gave a *combined* reaction in the original test, both the positive and the pseudoreaction may be detected. The positive reaction becomes manifest in the original test at the end of three to four days, when the pseudo-element of the reaction has disappeared, as a definite circumscribed area of redness, which measures from 1 to 2.5 cm. in diameter and shows superficial scaling with beginning brownish pigmentation. The pseudoreaction is detected in the control test with the heated toxin; the reaction will not be as marked as in the original Schick test, but passes through the typical clinical course of a false reaction.

FRACTURE OF THE GREATER CORNU OF THE HYOID BONE RESULTING FROM MUSCULAR ACTION *

H. P. ASHE, M.D., PITTSBURGH

Fractures of the hyoid bone due to muscular action are very rare. Stimson[1] mentions only two such cases out of forty-five hyoid fractures collected by Malgaigne, Hamilton, Gibb, Gurlt and himself.

The following case of fracture of the left greater cornu of the hyoid bone, having resulted from muscular action, will consequently be of interest.

Miss E. H., aged 29, domestic by occupation, called on me, Feb. 18, 1916, complaining of pain and swelling in the neck, and particularly of change of voice, the occasional absence of which so alarmed her as to be the incentive toward seeking medical aid.

The week previously, February 11, while engaged in the task of arranging portieres, she inclined her head forcibly backward, and at the time felt and heard, as she expressed it, "something break in the neck." Swelling of the neck anteriorly, localized pain in the neck produced by motions of the head or tongue, bloody sputum, deglutition embarrassed by frequent choking, and alteration of voice variously muffled, hoarse, or absent were the symptoms early manifested. Cough and dyspnea were not experienced.

The patient was a tall, healthy looking, well developed muscular young woman, whose past medical history was uneventful, barring a tonsillectomy and an appendicectomy undergone a few years previously, since which time she has enjoyed excellent health.

A very discernible, well defined swelling, without ecchymosis, occupied the anterior and anterolateral cervical regions, beginning sharply at the superior border of the hyoid bone, and continuing into and traversing the submental region as far as the inferior border of the inferior maxillary bone.

Emphysema was not present. The hyoid bone was well outlined on palpation, disclosing no perceptible irregularity, save a slight inward deviation of the left greater cornu. Pain and tenderness were elicited when pressure was made at a point on the bone near the juncture of its left greater cornu with its body. Slightly to the left of this point was a slightly enlarged, tender submaxillary lymphatic gland. Examination of the floor of the mouth and oropharynx proved negative.

As a week had elapsed since the occurrence of the accident, and as union takes place promptly in hyoid fractures, crepitus and preternatural mobility were not present.

The contours and external surfaces of the thyroid and cricoid cartilages were unaltered, and both could be freely manipulated without any pain or discomfort. At the time of the examination, the dysphagia, bloody sputum, and pain due to motion of the tongue had all disappeared, and, according to the patient, the cervical swelling was diminishing.

Further intended study of the case by laryngoscopy and roentgenography was prevented by failure of the patient, who lives out of the city, to report subsequently. March 6, information indirectly obtained revealed only that the patient was still hoarse.

The fact that this patient was treating the external swelling with liniments for a week prior to calling on professional aid, which would not have been sought had she not been frightened by occasional speechlessness, renders it strongly probable that fractures of the greater cornu of the hyoid bone sequential to muscular action are more frequent than shown by the literature, and warrants the belief that cases presenting as many symptoms as the one just narrated, not to mention cases manifesting more vague and fewer symptoms, occur and run their course without recourse to the physician or surgeon.

The treatment was expectant, the patient being ordered to refrain from use of the voice, and to secure approximate immobility of the head and neck by means of wearing a high, stiff collar.

1304 Colwell Street.

A CASE OF BOTHRIOCEPHALUS LATUS INFECTION

J. J. SINGER, M.D., ST. LOUIS

Assistant in Medicine, Washington University

Cases of *Bothriocephalus latus* infection are so rare in this country that it seems advisable to report all cases as they present themselves, if only to awaken interest and stimulate the search for others.

In 1904 Edsal[1] said that American literature does not provide a sufficient number of cases to indicate that the parasite is by any means common, but the authentic cases that he has found, together with a few reliable cases reported to him in private communications, led him to believe that those whose practices or hospital services brought them in touch with foreigners, especially Russians, Finns, and Swedes, are most likely to meet this parasite.

Many practitioners are content to make a diagnosis of "tapeworms," without identifying the species. This accounts for the small number of known cases.

At any rate, the *Bothriocephalus latus* is comparatively rare in this country, only twenty-two cases having been reported in America up to 1904. Since then there have been only eight other cases that I could find in the literature on the subject. Only one of these cases[2] was in an American-born boy, of Finnish parentage. This boy had never left the state of Minnesota. In all probability native foci may develop in the United States through the agency of our foreign-born element, and therefore it is necessary to report and follow up all cases if we wish to keep this parasite from getting a foothold in this country.

Nichorson believes that the probable reason that practically no cases develop in this country is our method of preparing fish for food, the larvae being destroyed in cooking. He states that he has frequently found the larvae of the *Bothriocephalus latus* in fish caught in the Great Lakes. Huber reports seven cases, seen in as many years, all of which were in Polish patients.

The case I wish to report presents nothing especially new. The specimen of the bothriocephalus is excellent.

The patient, Mrs. I. C., living in St. Louis, a native of Vilna, Russia, called at my office Jan. 23, 1915. She complained of indefinite pains in the abdomen, especially in the left side, lower quadrant. There was no fever or vomiting, she had a sensation of fulness in the stomach only slightly relieved by active purgation Her appetite was poor and she had been sleeping poorly, during the last few months she felt weak and depressed For the past few years she had noticed sections of tapeworms in her stools Sixteen years ago, she also passed sections of tapeworm, at which time she was given an anthelmintic, and passed a tapeworm 15 feet long, she did not remember whether or not the head was recovered She felt quite well for twelve years, when she again passed sections of the worm At this time she suffered with fainting spells and attacks, similar to the present

* Read before the Allegheny County Medical Society, March 21, 1916.

[1] Stimson: Practical Treatise on Fractures and Dislocations, Ed. 6, Philadelphia, Lea & Febiger, 1910, p. 180.

[1] Edsal: Am. Med., 1904, viii, 1087.

[2] This case was reported by Nichorson in 1906.

She was again given anthelmintics with no results From that time to this she has been passing sections at irregular intervals She never felt perfectly well A sister and her mother both had this parasite The patient states that it was the custom in their vicinity of Russia for everybody to take worm medicine

Physical examination revealed a small woman of fairly good color, the pupils reacted to light and accommodation, teeth fair, pharynx negative, no glandular enlargement, no enlarged thyroid Lungs and heart were negative abdomen very sensitive along the course of the descending colon The pelvis was negative except for some tenderness in the left adnexa Blood smears were negative, hemoglobin 90 urine negative, stools showed sections of *Bothriocephalus latus* and numerous eggs, temperature 98 4 pulse 76, respiration 22

She was ordered to take castor oil on the night of January 23, eat nothing but Holland herring, and drink considerable water On the 24th at noon she was given a 10 grain capsule of male fern every half hour until six were taken, four hours later 2 ounces of castor oil were given

At midnight of the 24th she was taken with severe cramps, followed by perspiration and severe diarrhea All the feces were collected Up till 12 o'clock on the 25th, ten stools in all were passed The stools were examined and 27 feet of the *Bothriocephalus latus* were recovered including the head The specimen was sent to the Washington University Museum

The following day the patient felt quite well her appetite was good and all tenderness had disappeared No eggs were found in the stools

Carleton Building

SPLIT TENSOR FASCIAE FEMORIS

Leo Bernd M D, Philadelphia

B W aged 18 in playing football had a dislocation of the right hip which was reduced without much trouble The hip continued weak and seemingly became dislocated on the slightest adduction The patient wore a cast for a month and then a brace In the fall of 1915 he tried to play football, but became so much worse that it came out even when he did the crawl" stroke in swimming

Roentgenoscopy revealed no abnormal condition of the joint in either abduction or adduction In consultation with W M Jackson Merrill a diagnosis was made of a split in the tensor fasciae femoris muscle which caused the trochanter to buttonhole through the split in the muscle The patient was anesthetized an incision over the trochanter was made, and a split in the muscle about 4 inches long was found Three mattress sutures of chromic kangaroo tendon were inserted, one continuous chromic catgut suture, three interrupted silkworm sutures through the skin and fascia, then a subcutaneous suture Gauze soaked in alcohol was used as a dressing A plaster cast from the knee over the hip was finally applied

At the end of two weeks the patient was discharged Four weeks later he was in swimming and going to dances with no return of symptoms The crawl" stroke swimming is the exercise advised as it is not a side kick, but an up and down motion of the feet and anterior muscles of the leg

The case is unusual, and unless the slit had been sewed up, the boy would have been an invalid, as he could not exercise and was becoming a nervous wreck

New Instruments and Suggestions

HYDROCHLORIC ACID AS A DECOLORIZING AGENT FOR THE TUBERCLE BACILLUS*

Robert A Keilty, M D, Philadelphia

The purpose of this paper is the determination of the value of hydrochloric acid as a decolorizing agent for the tubercle bacillus This acid has been used in my laboratory for over two years in the preparation of several hundred specimens These include blood, sputum, smears, urine, feces, tissues, both frozen and paraffin sections, and cultures

I believe that it is wise to use any method of technic, once established, without variation In this way it is possible to arrive at accurate comparative results Technics, too, should be carefully scrutinized for points of error, and after all possible sources of mistake are corrected, one may go ahead with any given line of work Nothing is more discouraging than to have an otherwise carefully prepared research clouded by faulty technic

In selecting a decolorizing agent one finds a great variety in use and the variations in the percentages advised are marked The methods range from a few seconds with 30 per cent nitric acid to an indefinite time with 1 per cent acid alcohol In my early work, I used Pappenheim's solution, which is both a decolorizer and a counterstain For the examination of routine smears I found this very satisfactory, but owing to numerous criticisms I decided to change

The various acids were tried and hydrochloric acid finally decided on This is not generally advocated and, so far as I know has never been suggested stronger than 25 per cent I started primarily with 30 per cent and have been using this routinely for the past two years, allowing it to remain in contact with the material thirty seconds by the watch Lately I have increased this to one minute, but I think that thirty seconds is sufficient for a properly prepared slide

In the determination of the action of hydrochloric acid on the tubercle bacillus I used (1) a fresh culture one month old isolated from the sputum, (2) one one year old originally isolated from the sputum and the transplant three months old and (3) fresh sputum From each of these fourteen slides were made They were stained five minutes with carbolfuchsin cold, the excess drained off and 30 per cent hydrochloric acid applied The first slide was washed off in one minute the second in two minutes and so on every minute up to ten, then fifteen twenty, twenty-five and thirty minutes were allowed, in order, for each of the remaining slides All were counterstained one minute with Loeffler s methylene blue

It was found that the tubercle bacillus retained its acid-fast properties in all instances, including thirty minutes' decolorization, with several variations In all a fading of the red in the bacilli is quite noticeable after five minutes There is a tendency to become refractile which is later lost Some bacilli retain a bright red color, especially the solid forms, while some at the same time have become mere shadows In proportion, at thirty minutes the shadowy forms predominate There is only a slight tendency to take on the blue color This is more noticeable in the old culture, which had some blue forms from the beginning Finally the old culture as a whole retained more of the acid-fast property than either the young culture or the sputum

I wish to call attention to the uselessness of heating carbolfuchsin in the preliminary stain This is an entirely unnecessary procedure in my experience, which covers several years in the use of cold stain The use of heat is one of those methods which is mechanically advocated by one textbook after another, is probably not practiced by most men doing considerable work, and is the source of much inconvenience to the man who has an occasional slide to examine

---

[*] Presented before the Philadelphia Pathological Society Jan 27, 1916

[*] From the McManes Laboratory of Pathology, University of Pennsylvania

I have not studied hydrochloric acid in relation to the other acid-fast organisms In thick smears and in sputum, after washing the hydrochloric acid with water, it may be necessary to run on a few drops of 95 per cent alcohol In most instances, and in thin smears, this is unnecessary, since the Loeffler's blue is an alcoholic solution and will, if allowed to remain three or four minutes, completely decolorize the thick areas

CONCLUSIONS

1 Make thin smears on slides, fix with heat, stain with cold carbolfuchsin five minutes, decolorize with 30 per cent hydrochloric acid thirty seconds or more by watch and counterstain with Loeffler's methylene blue

2 Thirty per cent hydrochloric acid for one minute will not decolorize any strain of tubercle bacillus with which I have worked

3 In this percentage and for this time hydrochloric acid will decolorize all artefacts such as rims of red blood cells, bits of leukocytes, granules of protoplasm and all ordinary nonacid-fast organisms

---

STABILIZED GENTIAN VIOLET

W D Stovall, M D, and M Starr Nichols, B S,
Bacteriologist and Assistant, Respectively, Wisconsin State Laboratory of Hygiene
Madison, Wis

Of the many stains which serve the bacteriologist in the capacity of a differential stain, there is not any single stain which has so wide an application as the one known as Gram's The only disadvantage in the use of the stain is that the gentian violet used deteriorates, and on that account should be freshly prepared when wanted In a laboratory in which smears for gonorrhea are examined at frequent intervals, it is quite a convenience to have the differential stain, Gram's stain, made up ready for use, and it was this necessity which led us to experiment with different formulas as well as with different organic preservatives in an effort to find a method of stabilizing the gentian violet solution

CHEMICAL

Gentian violet is a mixture of pentamethyl and hexamethyl pararosanilin, and belongs to the class of stains known as the triphenylmethane dyes In the manufacture of this dye it is prepared first as the colorless color base and then subsequently converted into the colored compound by treatment with hydrochloric acid This change is represented by the graphic formula (Fig 1) The hydrochloric acid neutralizes the hydroxyl group in the colorless base, and immediately the chlorin atom migrates from the position which the hydroxyl group occupied to the amino group, with a corresponding rearrangement of the intramolecular structure which gives the recognized quinonoid grouping If a solution of gentian violet is made alkaline with sodium hydroxid, the reaction is reversed and the colorless color base is again formed Anilin is one of the ingredients in the regular Gram violet solution, and on account of the amino group acts like a weak base The instability of the violet solution is therefore probably due in part to its action

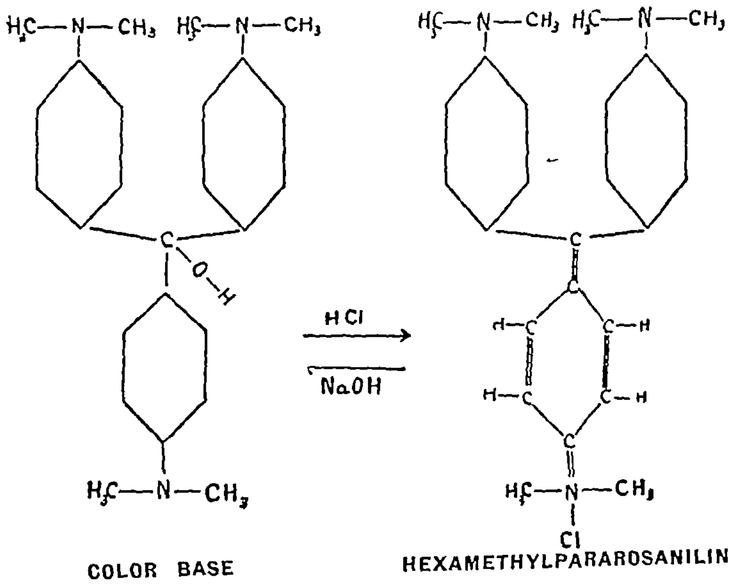

Fig 1 —Formula showing change

The ammonia of the air in the average laboratory probably also plays its role in decolorizing the stain To prove that small amounts of a base would destroy the color in the violet solution, a series of tests were made, and it was found that N/500 sodium hydroxid would precipitate completely in one hour the color from a 1 10 dilution of the regular violet stain, and that N/10,000 sodium hydroxid would precipitate completely the same strength solution in three weeks Along with the same series, a test with N/100 acetic acid in 1 10 dilution of the stain showed entire preservation after eight weeks' time These tests proved conclusively that the stain could be preserved with small amounts of acids

Fig 2 —Results of test

The next series of tests undertaken was to determine the concentration of acid which was best suited for this purpose Eleven different solutions were prepared, ten of which contained acid, while the eleventh was made in the regular manner except that no acid was added At the end of five months the gentian violet was determined quantitatively in each of the eleven solutions These results are tabulated in the last column of Chart 2 It will be seen that in no instance did any one of the solutions which were preserved with acid deteriorate below 62 per cent, while the average strength is about 85 per cent of the original strength On the other hand, the one which was not preserved dropped to 5 per cent of the original strength

BACTERIOLOGIC

At the time the foregoing stains were prepared, it was deemed absolutely necessary that the preserved stain be tested out on known gram-positive and gram-negative organisms To do this we used pus from a case of known gonorrhea containing the gram-negative diplococcus, typhoid culture (gram-negative), staphylococcus (gram-positive) and diplococcus (gram-positive) The four smears were placed side by side on each of eleven slides, and each slide stained in exactly the same manner Figure 2 gives the results of this test

From this chart we see that a high concentration of acid is objectionable, because the gram-positive organisms have a tendency to lose their stain Test Stain 9 was selected as the proper one for general use, as this showed practically no effect of acid on the staining quality Accordingly, a large batch of stain having the formula of the one tested was made up, and is the one which we use regularly in the laboratory in general diagnoses It has the following formula

Anilin	28 c c
Gentian violet (Gruber	6 gm
Alcohol 95 per cent	100 c c
N/1 hydrochloric acid	5 c c
Distilled water	q s ad 1 000 c c

The gentian violet is dissolved in the alcohol The hydrochloric acid is added to the anilin, and the whole is dissolved in enough water to make 900 c c The aqueous solution is filtered and added to the alcoholic solution of the stain The whole is filtered and is then ready for use

This stain keeps for about three months under ordinary laboratory conditions

A NEW APPARATUS FOR DRAINAGE OF THE PLEURAL CAVITY

William Lerche, M D, St Paul

After recent experience with a case of cancer of the esophagus in which I performed intrathoracic resection of the organ I decided in future similar cases to drain the pleural cavity for twenty-four hours after the operation The removal of the drainage tube, however would have to be effected without admitting air to the pleural cavity To this end I have devised a simple apparatus Although the apparatus was originated for intrathoracic surgery, it is in cases of empyema that I expect it to become of great practical utility, because it is easily applied under local anesthesia and the negative pressure which is essential to facilitate the expansion of the lung can easily be regulated

In Figure 1 are shown the details of the apparatus *a*, *a*, outer circular chamber in which the air can be rarefied by the suction bulb connected at *f*, thus fixing the apparatus to the skin, *b*, central chamber loosely filled with iodoform gauze around the drainage tube *c*, *c*, the drainage tube fitted air tight by rubber tubing at *e*, *d*, the rubber tubing connecting the drainage tube with a Woulfe's bottle, shown in Figure 2

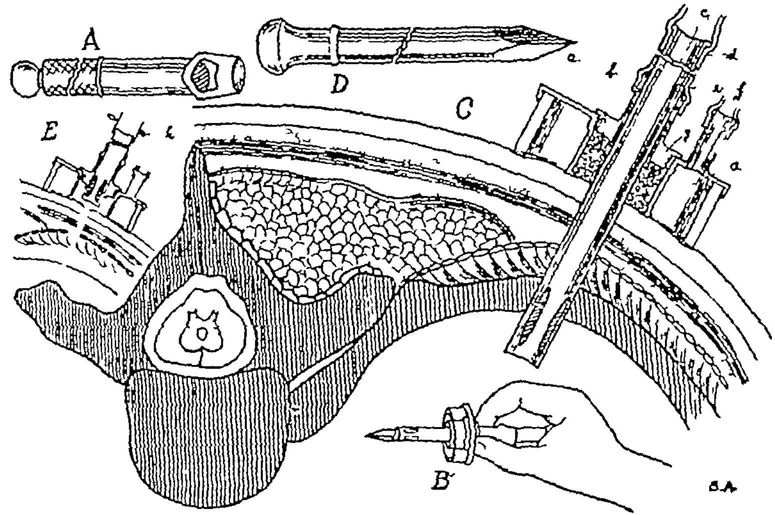

Fig 1 —Apparatus for drainage of pleural cavity *A* circular knife (28 French) for removing a circular piece of skin exactly corresponding to the size of the drainage tube *B* apparatus with trocar held ready for introduction *C* apparatus in position *D* trocar *E* position of drainage tube after its removal from the pleural cavity

In Figure 2, the apparatus, *a* is held in contact with the skin by rubber tubing, *b*, *b* *b*, encircling the body and over the right shoulder, and is furthermore glued to the skin by the aid of collodion applied to the bottom of the walls of the inner and outer chambers The rubber tubing and the collodion when dry are sufficient to hold the apparatus on air tight, but until the collodion has dried and when the drainage tube is being removed, suction may be applied by the aid of the rubber bulb, *j*, to prevent the apparatus from being pulled off The Woulfe's bottle, *e*, is provided with a quicksilver gage for the observation of the intrathoracic pressure The outlet from the bottle is at *f*, where a little valve (enlarged at *g*) fitted into the end of the rubber tubing prevents the air from returning to the bottle Instead of the valve a rubber bulb with a contrivance by which the air pressure can be regulated by a thumb screw, as seen in *k*, may be inserted at *f* When the intrathoracic pressure is as desired, the outlet of air can be shut off by the clip, *i* After drainage the rubber tube connecting the drainage tube, *c*, Figure 1 with the Woulfe's bottle is clamped, and tube *c* is withdrawn from the pleural cavity by a gentle rotary motion until its distal end gets some distance into the central chamber (as shown in *E*), where it is left until the wound in the chest wall has healed sufficiently to prevent air from entering the pleural cavity

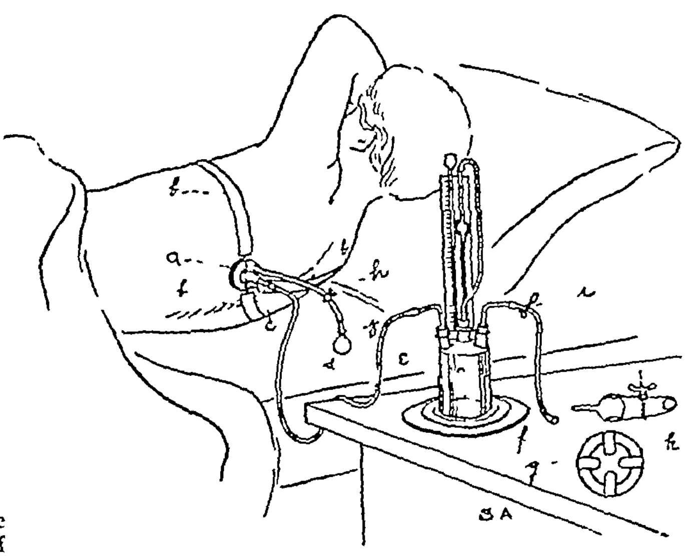

Fig 2 —Apparatus in position

The most comfortable position for the patient, after intrathoracic resection of the esophagus, is to lie on the right side half way on the back When therefore, the drainage tube is introduced into the pleural cavity before it is closed, as low down as possible and close to the mediastinum, it will drain at the most dependent point

In case of empyema, the drainage tube may be introduced between ribs or a rib may be trephined with an instrument corresponding in size to the drain

Campaign Against Blindness—The first annual report of the National Committee for the Prevention of Blindness covering the first ten months of 1915 has just been published This committee was formed to coordinate the activities of various local organizations It also carries on field and research work preparation of literature on the subject and the supply of lecture material for the publicity campaign Ophthalmia neonatorum and blindness due to alcohol have received most of the attention More than 90 per cent of the funds for the work were provided by the Rockefeller Institute and the Russell Sage Foundation The seventh annual report of the New York State Committee for the Prevention of Blindness is included with that of the national committee

AN ELECTRIC COLOR FINDER

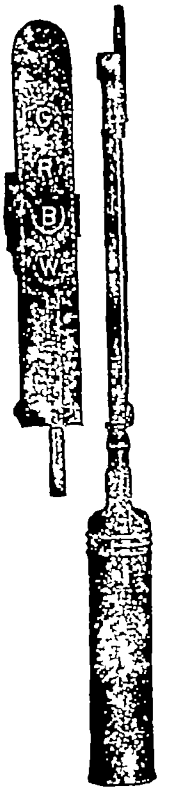
TO BE USED IN MAPPING OUT THE VISUAL FIELD AND THE BLIND SPOT

F Phinizy Calhoun, A B, M D, Atlanta, Ga

While I am not an advocate of electrically illuminated test objects in preference to the ordinary methods now used in mapping out the visual field and the blind spot, I believe such devices have their field of usefulness and can often be employed to advantage, for example, in office or dispensary work on dark days or in the evenings, and bedside examinations in poorly illuminated rooms or wards To meet such requirements I have devised, and used for nearly two years, an illuminated color finder patterned after the very excellent and well-known instrument of Dr Clifford Walker of Boston

The instrument is about 10 inches long, and the head contains four perfect colors (white, blue, red and green) made in thin paper and protected by layers of glass, arranged on a slide which is controlled by a thumb guide placed out of the way near the handle The thumb guide brings into view any one of the colored disks, which is illuminated by a miniature frosted lamp placed behind the color slide and supplied by a hand battery (or a rheostat attachment) There is an additional slide which fits on the face of the instrument and contains a 1, 2 or 3 mm opening The entire exterior is painted dull black and appears neat

I am indebted to E B Meyrowitz of New York maker of the instrument, for suggestions in its perfection.



Electric color finder

THE INTRAVENOUS USE OF MERCURIC CHLORID

A NOTE ON A NEW METHOD OF ADMINISTRATION, WITH SPECIAL REFERENCE TO PREVENTION OF VEIN OBLITERATION

P I Nixon, M D, San Antonio, Texas

Since salvarsan and neosalvarsan are no longer obtainable, the use of various mercury salts intravenously has become more widespread This method of treating syphilis is not new, the use of mercuric chlorid having been introduced by Baccelli in 1893 It has been revived from time to time, and each time abandoned because obliteration of the veins has been produced This is a definite disadvantage and a very possible danger, I myself have seen it eventuate in a local slough and edema of the forearm

Any method of administration, therefore, which promises to prevent or decrease the frequency of vein obliteration is to be welcomed The method which I am reporting is so simple that it is quite possible that it has been described before, it certainly is not in general use, and I have not been able to find a description of it in the literature It is infinitely more simple than the method described by Thompson,[1] and accomplishes the same purpose in a more aseptic and less painful manner It has the added advantage of using no heterologous serum

The method is as follows Mercuric chlorid, from one-tenth to one-third grain, depending on the dose, is dissolved in 10 c c of freshly distilled water and drawn into a 20 c c syringe The needle with the syringe attached is introduced into the vein, and 10 c c of blood are aspirated into the syringe The mixture is then injected in the usual manner, without withdrawal of the needle from the vein

It will be seen that the object of the method is to substitute the insoluble, comparatively nonirritating mercury albuminate for the soluble, irritating mercuric chlorid—a substitution which takes place in vivo when mercuric chlorid is injected directly into the vein I have found out experimentally that there is more than enough albumin in 10 c.c., or even 5 c c of blood to change the mercuric chlorid in the largest desirable dose, and Byrnes[2] has previously worked out the same problem

I have used this technic in fifty injections without obliterating a single vein To put the method to a thorough test, I have selected small lateral veins and at approximately the same point given as many as ten injections, at three day intervals, without disturbing the vein

One cannot hold that this method is established by this small series of injections In my hands it has been very satisfactory Its ultimate utility will be proved or disproved only after it has been tried out more extensively by different observers

205 Hicks Building

Therapeutics

HEMORRHAGIC CONDITIONS

VISCOSITY

By viscosity is usually meant cohesion between the particles in a fluid It is a physical characteristic of all fluids, and hence of blood It was thought that through a study of this property of blood some information of value in the diagnosis and treatment of disease might be gained

In order to obtain a relative value for the viscosity of blood, it is compared to distilled water, which is considered unity It has been found by means of various viscosimeters that the viscosity of blood in the normal person is between 4 5 and 5 5 This value may be influenced in various ways It has been found that cold baths increase and warm baths diminish the viscosity[3] Various diets continued over a period of time will also influence the viscosity of the blood Meat eaters show an increased viscosity, and vegetarians a lowered viscosity Heavy muscular work and profuse perspiration will increase viscosity, while the ingestion of large amounts of fluid will tend to diminish it[4] Whereas chloroform and ether have no effect on viscosity of blood, alcohol, no matter how introduced, whether by mouth or intravenously, will increase it

Heubner[5] calculated that from two thirds to three fourths of the viscosity of blood was due to the corpuscles This is proved by the fact that immediately after hemorrhage the viscosity is diminished In the anemias, even those associated with such chronic conditions as nephritis, cardiac conditions, tuberculosis or carcinoma, there is a diminished viscosity[6] In primary pernicious anemia it is unusually low, Austrian[6] finding it as low as 1 7 In all of these cases there was, of course, a diminished corpuscle content of the blood

In cases in which the number of corpuscles is increased, as in polycythemia, the viscosity is high In one case mentioned by Austrian, the red blood corpuscle count was over 8,000,000 and the viscosity 13 6 In diabetes mellitus, if polycythemia is present, the viscosity will be higher than normal

[5] Heubner, quoted by McCaskey (Footnote 2)

[6] Austrian Johns Hopkins Hosp Bull January 1911 p 9

In asphyxia or conditions in which there is associated dyspnea or cyanosis, such as decompensated cardiac lesions, pneumonia or emphysema, the viscosity is increased In jaundice it is also higher, owing probably to cholemia It is increased in arteriosclerosis, although it bears no relation to the blood pressure In typhoid fever it is unchanged, whereas in malaria it may be normal or subnormal, depending on the amount of anemia present

Perhaps the only time when an increased viscosity would be considered an important factor is when an increase may mean added work to an already weakened cardiac musculature Such would be the decompensated hearts, or in pneumonia, or where there is hypertension In the latter class of cases iodids are of value Boveri,[7] in a study of twelve cases, found that there was a marked diminution in the viscosity in eight of these cases following the administration of iodids It has also been shown that good hygienic treatment with plenty of fresh air will tend to lower the viscosity

BLOOD PLATELETS

Duke[8] has pointed out the importance of the blood platelet count in studying those pathologic conditions in which such an irritant as a chemical or bacterial toxin has entered the blood stream Blood platelets have an important function They have long been thought to be intimately connected with hemorrhagic diseases, and it has been supposed that they form a nidus from which fibrin extends in the formation of a clot Other factors such as antithrombin, prothrombin and calcium are also more or less disturbed in hemorrhagic diseases They appear to be closely associated with the blood platelets, or some substance produced by the blood platelets, since the latter disintegrate during normal coagulation of the blood

Duke[9] believes that purpura hemorrhagica "is due wholly or entirely to an almost complete absence of blood platelets from the blood" He has shown that although the coagulation time may be normal, the bleeding time is prolonged The bleeding time is determined by blotting up on absorbent paper at half minute intervals the blood from a bleeding point The rate of decrease in size of the blots gives an index of the rate of decrease in the intensity of the hemorrhage Duke quotes many others who also found a decrease in the number of blood platelets in purpura hemorrhagica

Unless stained immediately after obtaining the blood, blood platelets will degenerate rapidly They stain blue or violet with the usual stains, and are about one fourth to one half the size of a red blood corpuscle They contain no nucleus and no hemoglobin

Brockbank,[10] after carefully studying stained blood smears, states that the blood platelets originate from the red blood corpuscles Wright[11] thinks that they are derived from large giant cells, called megakaryocytes, found in bone marrow The normal blood platelet count varies between 150,000 and 500,000 It may vary in normal conditions In the new-born child after the first week the number is nearer the upper border of the normal count, that is, about 400,000 During menstruation it may be below normal

It is interesting to follow the blood platelet count in some of the pathologic conditions Duke[9] states that Osler, Riess and others have found a reduced number in pernicious anemia Others have found the count low in pneumonia, lymphatic leukemia, aplastic anemia and typhoid fever Dimon[12] states that in splenomyelogenous leukemia there is a high count, from 500,000 to 1,000,000, while in lymphatic leukemia the platelet count may be reduced to between 30,000 and 150,000

Duke[8] states *that there is a general agreement* that during febrile periods of acute infectious diseases the count is reduced, whereas during convalescence it is increased He cites, as an example, diphtheria, in which, during the febrile period, the count in one case was 3,000, and during convalescence as high as 750,000 In chronic tuberculosis the count is usually high, even going above 1,000,000 In occasional cases it may be low This is also true of chronic nephritis In other conditions, like pneumonia and typhoid fever, the count is reduced Duke explains these counts by assuming that in those cases in which the count is high, only a mild irritant is produced which has no strong toxic action on the blood-platelet forming organs On the other hand, in cases in which the number is reduced, the toxin produced exerts a powerful irritant action He proved these assumptions by finding the platelets reduced after injections into animals of diphtheria toxin, killed typhoid bacilli, benzol (benzene, C_6H_6) and tuberculin

(To be continued)

ACIDOSIS AND THE DIARRHEAS OF INFANCY

Acidosis is being much discussed in relation to the pathologic phenomena associated with it Only a few years ago the term was usually limited to those abnormal manifestations of the presence of acetone, diacetic acid and betahydroxybutyric acid which are now more appropriately classed under the designation of ketone substances, the immediate causes of ketonuria or acetonuria Subsequently acidosis was the name also applied to a condition in which the increased elimination of ammonia by the kidneys indicated the abnormal accumulation of acids, not necessarily of the group just referred to, somewhere in the body The ammonia, acting as a neutralizing base, furnished an index of the occurrence of undue quantities of acid somewhere in the metabolic cycle

From the broader standpoint of today it is conceivable that acidosis may result when any abnormal acids, such as betahydroxybutyric or lactic acid, are produced in excess in the body It is possible also that acidosis may result when bases are lost from the body to an exceptional degree Finally, an added category is suggested by the possibility that some types of acidosis may be associated with the failure of the acid excretory function of the kidney Under ordinary conditions much acid is eliminated, chiefly in the form of acid phosphate, by renal activity, as the usual preponderatingly acid reaction of the urine testifies A failure of this special regulatory function of the kidney would result in a retention of acid phosphate with a consequent true acidosis

An exceptionally interesting instance of an acidosis, which may prove to be of the renal retention type, has been described by Howland and Marriott[1] of the Harriet Lane Home and the Department of Pediatrics of the Johns Hopkins University It attends attacks of severe diarrhea not of the ileocolitis type in infants The various signs now recognized as indicative of a disturbance in the acid-base regulation have been detected in suitable cases Thus alterations in respiration are observed, the usual abdominal type of breathing by the young being succeeded by one which is both costal and abdominal Again, a lowered tension of carbon dioxid in the alveolar air, likewise a symptom of acid intoxication,[2] is found in the diarrheal cases, sometimes even when a distinct hyperpnea could not be definitely detected The infants here concerned may further have a greatly increased hydrogen ion concentration in the blood serum, and the acidosis may also be revealed by a diminution of the alkali reserve of the serum, an increase in the amount of alkali required to alter the reaction of the urine (alkali tolerance), and by a diminution of the combining power of the hemoglobin with oxygen

The time has passed when all types of acidosis are to be interpreted in the same way Howland and Marriott have furnished reason for believing that in the cases of infantile diarrheas to which they refer the acidosis is not due to the presence of acetone bodies It has not been demonstrated that it is due to loss of base Probably it is due to deficient excretion of acid phosphate by the kidneys At any rate, this at present appears to be the most likely explanation It is known that in severe diarrhea, the urinary secretion may be markedly diminished even to the point of complete anuria, the kidney becoming functionally more or less inactive, even though no organic changes may be present That diminished acid excretion and consequent retention of acid phosphate in the body fluids would occur under these conditions would seem probable In support of the hypothesis is the finding of an increase in the phosphate content of the blood serum in the course of severe diarrhea

The hypothesis outlined suggests a tentative method of treatment All measures should, of course, be used to prevent the cessation of renal activity, especially since the secretion of urine is often very scanty and often ceases for hours at a time The best of all procedures is the constant administration of water or salt solution by mouth if possible, if vomiting prevents this, as it frequently does, water must be given by rectum, subcutaneously or intravenously But beyond these obviously desirable measures, as well as the accepted methods of controlling the excessive diarrhea itself, the existence of an acidosis, as seen in the hyperpnea or other more accurate signs, should be energetically combated Alkalies, such as sodium bicarbonate, must be freely administered in any effective way until the reaction of the blood is again normal Large doses may be required The results of such treatment, vigorously applied, are reported to be encouraging As Howland and Marriott point out, the condition resulting from the acidosis or accompanying it is most serious even if its exact nature is not understood Therefore, they add, in all cases of severe diarrhea, even though there are no evidences of acidosis, it is advisable to use sodium bicarbonate until the urine is alkaline Its administration may prevent the development of acidosis When further observations have made clear the processes on which the acidosis depends, we may be able to direct our treatment more intelligently At present we are forced to combat the result and not the cause It is certainly a helpful step in the direction of progress, however, to have some scientifically justifiable evidence on which to base a therapeutic program for these severe diarrheas, even if further researches shall lead to a modification or reversal of the plan of treatment

VACCINE TREATMENT

Looking backward over the development of active immunization by vaccines during the last fifteen years, we appear to be at the termination of one epoch in the therapeutics of infectious disease In this issue, Hektoen[1] traces the stages by which vaccines which were first employed with attempted scientific control have come into indiscriminate and unrestrained use, with no guide beyond the statements which commercial vaccine makers are pleased to furnish with their wares Already most physicians are realizing that the many claims made for vaccines are not borne out by facts, and that judging from practical results there is something fundamentally wrong with the method as at present so widely practiced As clearly shown by Hektoen, "the simple fact is that we have no reliable evidence to show that vaccines, as used commonly, have the uniformly prompt and specific curative effects proclaimed by optimistic enthusiasts and especially by certain vaccine makers, who manifestly have not been safe guides to the principles of successful and rational therapeutics "

But out of this wild period from which we are emerging there have come certain benefits which promise to be more or less permanent The study of prophylactic immunization against typhoid and other similar diseases has been fostered, and the time of attainment of its present efficacy perhaps hastened, the effects of active immunization in accelerating the development of immunity and recovery in certain chronic localized infections of known etiology have been studied, the search for sources of infection from which autogenous vaccines could be obtained has led to a more careful examination of patients, who have thus been indirectly benefited by having the source of their troubles discovered and removed

It has been difficult for most physicians to distinguish between the relatively limited field of prophylactic immunization in which scientifically controlled experiments and carefully observed and analyzed results have confirmed the claims of the method, and the other field of the use of vaccines in which mixtures of bacteria and their products have been indiscriminately introduced into patients suffering from all manner of disease, infectious and noninfectious, acute and chronic, without study of the patient, or knowledge of the etiology or pathology of the disease But the latter use of vaccines cannot be condemned merely on the ground of its empiricism As Theobald Smith has said, "We cannot do without empiricism wholly We owe valuable suggestions and discoveries to it These are like clearings in the forest unconnected with other clearings, but destined to become the nucleus of a healthy scientific growth " When, however, it becomes evident that empiricism has run riot, that it has wholly divorced itself from scientific control, and when, in addition, its results, impartially reviewed, are shown to be unbeneficial, we must conclude that such a clearing has been badly located, and that it never can occupy a worthy place on the highway of scientific medical progress

In regard to the more recently developed methods of intravenous therapy in typhoid fever, Hektoen points out that certain new concepts and theories are introduced which need diligent study and correlation before their application to the problem can be settled Here again we find ourselves in another pioneer clearing in an unexplored forest Only the future can determine whether this clearing is to become a useful station, or whether after a brief existence as a point of interest it will prove to be far removed from the thoroughfare of legitimate travel Certainly the development here should proceed cautiously

Already a similar procedure has been introduced for the intravenous treatment of other subacute and chronic infectious diseases, such as arthritis, and some observers have asserted that the amelioration of the symptoms in the joints following the treatment is sufficient to establish it as a worthy routine treatment The fact that in the subjects of arthritis and even in normal persons the intravenous injection of bacterial or other protein is followed by a rather characteristic sequence of phenomena of fever, chill and leukocytosis by no means stamps the method as a justifiable type of empiricism Indeed, other observers have noted that patients so treated relapse, and that the number of those who do not relapse is apparently no greater than the number of untreated patients who recover spontaneously Such treatment, ineffective in itself, actually hinders recovery by distracting attention from the search and removal of the cause of the arthritis

The fact that much time and effort of the past ten years appear now to have been wasted, so far as positive results go, should make us doubly cautious in accepting a new and somewhat similar procedure until opportunity has been afforded for its verification under conditions favorable for scientific control

FACTORS CONCERNED IN WATER PURIFICATION

The amount of water needed by large communities for varied purposes is decidedly greater than is suspected by those not familiar with the problems of municipal water supplies The estimates made in different cities to meet all legitimate requirements place the quantity at not less than 750 quarts a head, daily A large part of this is, of course, devoted to other than domestic purposes — to manufacturing, sprinkling and fire protection, for example Such water would not necessarily be expected to have the same degree of purity as that required for household uses and drinking purposes As usually it is not convenient or practicable to have separate supplies for the specific needs in the present stage of water supply management, the source of supply must generally be considered as a single problem The surface area that is necessary in order to furnish a supply sufficient for a large city is correspondingly enormous

As a result of these conditions, not infrequently watersheds which provide the larger supplies cross the borders of individual states The problems of pollution thus become complicated by the intricacies of interstate relations, which are frequently the subject of legal and political disagreement An exceptionally prominent instance is afforded in the case of the city of Washington This is outside the jurisdiction of the surrounding states It derives its water supply from the Potomac River, which drains an area extending into several states The city discharges its sewage products ultimately into the same stream, which, in turn, is the source of edible shellfish that can carry infection A comprehensive examination of the sanitary problems of the Potomac River, therefore, has features of widespread importance It involves the question of pollution, direct or indirect, of navigable waters of the United States, and implicates certain sanitary features which because of their magnitude or character, are national in scope, and the solution of which devolves on the federal government

Several years ago a comprehensive study of the subject was undertaken by the U S Public Health Service This study was prompted by the publication of statements to the effect that the sewage from the city of Washington and other communities along the Potomac River polluted the waters of the lower river, producing danger of water-borne diseases, such as typhoid fever, by the eating of raw oysters taken from the oyster beds in the lower river These beds are extensive, as they may be found from Lower Cedar Point, about 65 miles below the sewer outlets of Washington, to the mouth of the river, which is about 100 miles below the outlets The District of Columbia was interested both because many of the oysters from the lower river are distributed and consumed in Washington, and because suggestions had been made that an elaborate sewage-disposal plant, to cost several million dollars, be installed for the treatment of Washington sewage Although many exhaustive studies of pollution of rivers and shellfish beds and many studies of industrial wastes have been made, few if any investigations have included the study of an entire river over a period of a year, and a still smaller number have embraced so many of the problems involved in the pollution of rivers

The coordinate effort of the federal government to collect and interpret sanitary data of the Potomac River as a whole so that the interplay of the various factors could be comprehensively understood is timely It is an appropriate extension of earlier important, though far less comprehensive, examinations of more limited questions, such as the influence of the water supply on the prevalence of typhoid fever in the District of Columbia [1]

The Hygienic Laboratory of the U S Public Health Service has now made public the results of the investigation[2] of the pollution of the Potomac River and its tributaries which was begun by the Public Health Service June 2, 1913, and continued until May 31, 1914 The investigation included a sanitary survey of the Potomac River watershed and laboratory studies of the water, mud, plankton and shellfish The sanitary survey included investigations as to the number of persons on the watershed, the prevalence and distribution of typhoid fever, the water supplies, sewage-disposal systems, and character and amounts of trade wastes

As a result of the survey, it was found that about 94 7 per cent of the population were served by public water supplies, and that a smaller proportion, 38 per cent, were served by sewage-disposal systems While typhoid fever was especially prevalent throughout the upper basin, the installation of water and sewerage systems and the increased activity of state and municipal health authorities have been followed by a decreasing typhoid rate, especially in the urban population, and the disease is now chiefly a rural one

Among the more detailed findings in the report on the Potomac problem is the evidence that at no point above Washington is the water of the Potomac River safe for use as a public water supply without reasonable treatment. Even during the period of lowest stream flow and highest temperature, the river in the area of heaviest pollution — that is, between Giesboro Point and Fort Foote — has at all times sufficient oxygen available for the sewage now discharged into the

river, and enough to take care of the sewage which will probably be added for several years to come.

Oysters in the lower reaches of the Potomac River form the basis of a large and important industry. Large numbers of men gain a livelihood from this source and the product is shipped, chiefly through Washington and Baltimore, to many parts of the country. In order to protect the ultimate consumers of the oysters, and thereby protect the industry itself, it is essential that the sanitary quality of the shellfish be known, and when necessary improved and protected. The oyster beds extend from the mouth of the river about half way to the city of Washington. In the upper few miles they are used almost solely for the growth of spat, and the oysters developing here are used chiefly for planting the lower beds, and rarely reach marketable size. From data on pollution and purification of the river, detailed in the preceding sections, it is evident that by the time the water reaches the area of the oyster beds it has undergone its maximum purification. Although during the winter months the increased stream flow shortens the time during which purifying agencies may act, any anticipated danger of pollution of shellfish from this cause will be shown to be without foundation. It is gratifying to learn that in an examination of oysters from all the beds in the whole river and its tributaries, extending over an entire season, no dangerously polluted oysters were found in the Potomac River proper. The very few polluted samples found came from localities from which few oysters are shipped.

The government bacteriologists have pointed out that the factors concerned in the purification of streams as it occurs in Nature are many, but are reducible on analysis to two main elements — the dying off of the bacteria of pollution and the oxidation of the organic constituents. All agencies of purification require time for their action, and in flowing streams it is important to appreciate the fact that it is the distance in time between successive points of observation and not the distance in miles which is significant. Moreover, the death rates of bacteria in water and the rapidity of oxidation are influenced by the temperature.

The report of the Hygienic Laboratory concludes that notwithstanding the especially favorable natural conditions attending the present disposal by dilution of the sewage of the District of Columbia, it is inevitable that, in consequence of a continued increase in the population of the District of Columbia, the capacity of the river to dispose of sewage without nuisance or danger will eventually be overtaxed. It is desirable, therefore, that primary treatment works should be installed in the near future sufficient to clarify the sewage up to the limits to which plain sedimentation may advantageously be carried. The cost of construction and operation of these treatment works would not be such as to be prohibitive when considered in connection with the benefits to be derived. They should be so designed as to work in harmony with the favorable conditions locally afforded by Nature for sewage disposal. These works should be sufficient to maintain a reasonable constant as to the amount of organic matter dependent on the river for purification. Their construction is also desirable in recognition of the advancing standards as to hygienic cleanliness of river waters, as well as for the example in such matters which should be afforded by the national capital.

STRAY DOGS, THE PUBLIC HEALTH AND PUBLIC DUTY

The association of rabies with the presence of our canine population was one of the first experiences which brought home the possible necessity of paying some attention to the uncurbed liberty of this loved and hated domestic animal. Rabies appears as an easily preventable disease when one recalls that such a minor restraint on the dog as muzzling was sufficient to eradicate it from England. By rigid enforcement of muzzling ordinances, rabies has also been practically or completely eradicated from the Scandinavian countries.

Although the foregoing feature of danger and the possibility of relief are at length rapidly being appreciated in the United States, it is not equally understood that the dog may also be of major importance as a carrier of parasites dangerous to man and the domestic animals. A zoologist in the Bureau of Animal Industry[1] has compiled the list of important diseases and parasites which are conveyed by the dog to man and the domestic animals, and which are present in this country: rabies in man and stock, hydatid in man and stock, gid in stock (and possibly also in man), muscular cysticercosis, or so-called "measles," in sheep, muscular cysticercosis, or "measles," in reindeer, cysticercosis of the liver and mesenteries in stock, tapeworm in man, especially in children, roundworm in man, tongueworm in man and stock, and fleas and ticks which transfer from dog to man and which may in this way transmit disease and parasites. Furthermore, in the recent outbreak of foot-and-mouth disease, it was determined beyond any reasonable doubt that dogs were responsible in some instances for the spread of the disease, not only from one farm to another, but also from one state to another.

It is unnecessary to elaborate the details of the harmful results here indicated as a possible outcome of the unrestrained wanderings of "man's faithful servant." We must not let either a maudlin sentiment or an unwholesome indifference blind us to the duty of modern communities and the rights of their citizens to live amid a minimum of preventable menaces to health and happiness The family dog, properly restrained and kept where he will not even become a potential danger to the other members of society, needs no severe indictment at this time But the case against the unrestricted, vagrant, ownerless stray dog is based, says Dr Hall,[1] on two counts — that he is a nuisance and that he is dangerous Speaking with the authority of expert knowledge, Hall adds that the stray dog which recognizes no owner must be eliminated The irresponsible dog, with no owner to care for him, to look after his health as it concerns the dog and other animals and man, and to restrain him and stand sponsor for his acts and especially the damage he may do, does not fit into a scheme of civilization which is based on law and the responsibility of individuals for themselves and others Of course, a little serious consideration of the actual hygienic value of a restriction of the dog's unwarranted liberty must suffice to convince any thoughtful person Usually, however, no reform in established customs can make great headway without a vigorous campaign of education to justify it Are we not ready for this? Need we hesitate to agree with the government experts that "the time seems to be at hand when the stray dog, the sheep-killing cur, the vagrant carrier of dangerous parasites and of the horrors of rabies should be exterminated? The destruction of such dogs would mean a saving of hundreds of lives and the saving and making of millions of dollars" Let us believe that this is not an age of indifference

Current Comment

CENSUS BUREAU LIFE TABLES

The Bureau of the Census of the Department of Commerce is about to publish a set of life tables for the United States compiled by Prof James W Glover of the University of Michigan These tables are unique in that they deal with the whole population of the region covered instead of being, as are the actuary tables of insurance companies, restricted to selected lives Death rates and the expectation of life are shown, at all ages, for the population of the original death registration states, namely, the six New England states, New York, New Jersey, Indiana and Michigan The basis of computation is the population as shown by the census of 1910 and the mortality for the years 1909, 1910 and 1911 Examination of these tables brings out, once more, the familiar fact of the greater longevity of women It is shown that, taking all races together, the expectation of life of a female at birth is more than three and one-half years greater than that of a male This difference persists throughout life, and in the case of native white persons, up to the age of 94 The death rate in the first year of life is more than 20 per cent higher among native white boys than among girls Of equal importance and interest are the figures for infantile mortality, 5 per cent of native white boys and 4 per cent of girls die in the first month, 12 6 of the former and 10 5 of the latter during the first year This high rate falls for both sexes to a minimum about the twelfth year, after which it again rises gradually The relatively lower mortality among rural residents is strikingly brought out by these tables The expectation for white males at birth in rural localities is 7 7 years greater than in cities At the age of 39 there is still a margin of five years in favor of the country Thereafter the difference diminishes, but the country holds the lead until the age of 88, when the urban residents commence to have slightly the advantage These few figures have been extracted to illustrate the nature of these remarkable tables The bulletin in which they are published contains sixty-five pages of information of direct interest and utility to the physician, and is offered by the government to the medical profession gratuitously[1] These tables are intended primarily to be of service as a source of information to the public They should be particularly useful to public health officials, students of vital statistics, physicians, sociologists, actuaries, statisticians and others interested in the improvement of the public health of the nation Their uses for legal purposes, valuation of reversions, annuities, retirement funds and old age pensions are obvious

KIDNEY METABOLISM IN NEPHRITIS

The ultimate source of the work done in the process of secretion by glandular tissues lies in the chemical energy utilized in the cellular functions It is not an easy task to estimate this change in a quantitative way The energy at the disposal of the cells is derived from the oxidation of complex organic compounds to products of low chemical potential value, such as carbon dioxid and water Oxygen is requisite for the continuance of such activities, and the measurement of oxygen consumption by a gland gives some indication of the nature and extent of its cellular reactions The expenditure of energy required for a particular sort of activity can be determined indirectly by measuring the difference between the oxygen consumption of the resting and the active organ under investigation Most of our knowledge in this field is due to the work of the English physiologist Barcroft and his co-workers Their measurements consisted essentially in determining the oxygen content of the arterial blood supplied to this organ, and the oxygen content of that leaving it by the vein, together with the amount of blood passing in a given time In a study of the gaseous metabolism of the kidney, Barcroft and Brodie[2] found that, taking all the experiments together, the output of carbon dioxid was equivalent to that of the oxygen taken in The respiratory quotient, CO_2/O_2, is therefore practically unity, as it would be from the oxidation of carbohydrate alone This result supports the belief that the substance oxidized in the functioning kidney is of a carbohydrate nature and that it is completely oxidized in the processes connected with secretion It is not unlikely that glucose is here concerned Recently the known facts regarding the vascular and metabolic conditions in the kidneys have been extended by an investigation of the oxygen consumption in nephritis of the type induced in rabbits by uranium salts[3] In these cases the histologic examination of the kidneys showed that the spaces round the glomeruli were much enlarged, the glomeruli themselves being shrunk There was some breakdown of the convoluted tubules, the other parts of the tubules being unimpaired The blood vessels contained an abnormal quantity of blood, the corpuscles in many cases forming a lining to the vessels In spite of this fact the blood flow was if anything faster than in the normal rabbits, the oxygen consumption was lower (0 046 c c per gram per minute as compared with 0 082 c c), and the venous blood emerging from the kidney was markedly redder The evidence thus obtained in the domain of cellular metabolism corroborates the known facts regarding the lessened work of the nephritic kidney as judged by quite different criteria

THE TYPHOID RATE IN PITTSBURGH

Owing to a misstatement in the number of deaths originally reported to us by the office of the Department of Public Health, Pittsburgh, the rate for this city for 1915 appeared in our recent summary as much higher than was actually the case The number of deaths as first reported to us was 159 The actual number, as given to us this week in a letter from Dr Edwards, director of the Pittsburgh Department of Health, was 59 The rate should consequently be 10 3 instead of 24 7 This correction raises Pittsburgh from ninth to seventh place in Group 1, and marks the lowest point reached in the history of the city Although this error was not made in The Journal office, we are glad to give special publicity to the excellent record made by Pittsburgh in 1915 The corrections in other averages, made necessary by the newer return from Pittsburgh, will be made *in our* next summary

Death Rates—It should not be understood, however, that the death rate *from the infectious* diseases *is* a measure of individual, so much as of community, intelligence In this country the wonderful reduction in the death rate from infectious diseases in the past fifteen years has been confined largely to the great cities Smaller cities, villages and rural communities have *improved* but little The larger cities are establishing effective health departments Building regulations prevent the construction of unsanitary houses, either public or private. Schoolchildren are inspected by competent medical men and first cases are detected and isolated Proper hospitals for the infectious diseases are provided and scientifically administered The children of the poorest and most ignorant go to sanitary school buildings and when infected, are scientifically treated The health officer of the smaller city is a joke and that of villages and *rural communities* exists, for the most part, only in name—Vaughan

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest such as relate to society activities, new hospitals, education, public health, etc)

ARKANSAS

Eradication of Malaria—Two communities in the state, one urban and one rural, namely, Crossett, Ashley County and a district in Chicot County, including the Red Leaf plantation, have been selected as sites for the model demonstration areas for the control and eradication of malaria under plans outlined by Surg Rudolph H von Ezdorf, U S P H S The work will be along the lines of drainage, screening and the eradication of mosquitoes The supervision will be maintained for two years and it is expected to demonstrate that malaria can be eradicated by making each of the test communities 100 per cent proof against malaria

State Society Meeting—The fortieth annual meeting of the Arkansas Medical Society was held in Texarkana, May 2 to 4, and the following officers were elected president, Dr Merriman L Norwood Lockesburg, vice presidents, Drs James M Lemons, Pine Bluff, W A Purifoy, Chidester, and William R Brooksher, Fort Smith, secretary, Dr Clinton P Meriwether, Little Rock (reelected), treasurer and editor of the *Journal of the Arkansas Medical Society,* Dr William R Bathurst, Little Rock (reelected), councilors, second district, Dr Joseph C Cleveland, Bald Knob, fourth district, Dr William Breathwit, Pine Bluff, sixth district, Dr John H Weaver, Hope, eighth district, Dr Earle H Hunt, Clarksville, and tenth district, Dr Joseph T Clegg, Siloam Springs (reelected), delegate to the American Medical Association, Dr Clinton P Meriwether, and alternate, Dr Robert Caldwell both of Little Rock. Little Rock was selected as the place of meeting for 1917

Free Clinic at Hot Springs—Through the efforts of Dr Loyd Thompson of Hot Springs and Dr William P Parks, superintendent of the United States Hot Springs Reservation, a free clinic has been established at the government free bath house The purposes of this clinic are to furnish free medical aid to the indigent patrons of the government free bath house, to study the clinical efficacy of the waters of the Hot Springs and to exclude from the bath house cases which might menace the safety of its patrons The following clinics will be maintained for the present medical, dermatologic and syphilis genito-urinary and neurologic The medical clinic will be under the direction of Drs William H Deaderick and John M Proctor, the dermatologic and syphilis clinic under the direction of Dr Loyd Thompson the genito-urinary clinic under the direction of Drs Edward H Martin and Ernest A Purdum, and the neurologic clinic under the direction of Dr James L Greene Assistants to the various clinics will be chosen from among the physicians of the city Dr William H Deaderick was elected chief of *the clinic and Dr Loyd Thompson, secretary*

DISTRICT OF COLUMBIA

Washington's Baby Week.—Baby Week was scheduled to close on May 13, but to meet a popular demand the exhibit was kept open on Sunday May 14, and ministers, physicians and others delivered addresses there on that day A novel feature of Baby Week as celebrated in Washington was a portable exhibit in charge of a trained *nurse, used for demonstrations in various* parts of the city This served not only to instruct those who saw it but also to interest them and their friends and acquaintances in the Baby Week *exercises generally*

ILLINOIS

State Laboratory Branch Opened—A new branch laboratory of the state board of health was opened, May 15, at Champaign under the charge of Dr F S Sperry The new laboratory is to be known as the East State Laboratory

Military Medicine—A series of lectures on military medicine under the auspices of the St Louis Medical Society was inaugurated, May 11, when Lieut -Col Thomas U Raymond, M C, U S Army, spoke on "The Military General Hospital", Lieut William A Hardaway, M R C, U S Army, presided May 18, Maj James M Kennedy, M C, U S Army, spoke on "Medical Service in Campaigns, Including Field Hospitals and Sanitation", May 25, Capt Frank N Chilton, M C, U S Army, will speak on "Medical Service in the Tropics", on June 1, Lieut -Col Thomas U Raymond, M C, U S Army, will discuss "The Medical Supply of an Army", June 8, Capt Will L Pyles, M C, U S Army, will consider "The Food and Water Supply of an Army and the Disposition of Waste at Camp", June 15, Capt Charles E Freeman, M C, U S Army, will review from a military standpoint "Preventable Diseases, Including Venereal Diseases, Alcoholism and Other Drug Habits," and on June 22, Maj James M Kennedy, M C, U S Army, will deliver the final lecture of the series on "The Recruitment of an Army and the Relation of the Medical Department to it, Including Moral, Mental and Physical Training of a Soldier, and the Relation of Clothing and Equipment to the Efficiency of a Soldier"

NEBRASKA

State Association to Meet—The annual meeting of the Nebraska State Medical Association will be held at Omaha, May 23 to 25, under the presidency of Dr Edward W Rowe, Lincoln, with headquarters at the Hotel Fontenelle

Hospital News—Bids have been asked by the board of control for the construction of a new three-story building at the Norfolk State Hospital, to accommodate 100 patients The plans include a large enclosed porch on each floor——The new hospital recently built at Wayne by Dr Anson S Lutgen was opened for inspection, April 7 and 8

Personal—Dr Robert Retzer, dean of the Creighton University Medical College, Omaha, has resigned——Dr George E Charlton, Ingleside, for many years second assistant physician at the Ingleside State Hospital, has been appointed superintendent of the Norfolk State Hospital, succeeding Dr William D Guttery

NEW YORK

Sanitary Officers to Meet—Saratoga Springs has been selected as the place for the 1916 convention of the New York State Sanitary Officers Association, which will meet in June under the presidency of Dr Montgomery E Leary, Rochester

New York City

Honor to Pilcher—The celebration of the semicentennial of the entrance into the professional field of Dr Lewis Stephen Pilcher, Brooklyn, continued from May 11 to 13 On these days surgical clinics were given in all the principal hospitals of the burough May 12, a banquet and reception was tendered Dr Pilcher by his associates and friends in the medical profession, in club life and in Grand Army circles

Red Cross Hospitals—The New York County branch of the American Red Cross, which has been working for some time for funds to establish three military base hospitals in this city, announces that gifts amounting to $50,000 have been received and that orders have been placed for the equipment of two base hospitals, of 500 beds each Efforts are now being made to obtain funds for the equipment of the third hospital Three full staffs of surgeons, nurses and orderlies have been organized for these hospitals under the direction of Dr George E Brewer, Dr George D Stewart and Dr Charles L Gibson

How to Feed the Family—This is the title of a little booklet published under the auspices of the Public Health Education Bureau of the Department of Health It presents a list of foods and the recipes for their preparation which will provide sufficient food for a family of five at a cost of $7 31 per week Careful attention has been given to the proper balance of the different food elements and the list has been tested practically for about two years by the Social Service Department of the Beth Israel Hospital The health department is desirous of spreading this knowledge since they find that many instances of malnutrition encountered in the clinics are due to ignorance as to what constitutes a proper diet

Dr Jacobi's Birthday—Dr Abraham Jacobi celebrated his eighty-sixth birthday anniversary, May 6 A dinner was given in his honor at the Ritz-Carlton by the board of directors of the Hospital for Deformities and Joint Diseases in which Dr Jacobi has taken great interest from its start in 1907 Contributions of $112,000 were received toward the $1,000,000 fund for the institution Dr Jacobi was presented with a gold-handled cane on behalf of the board of directors by Paul M Herzog May 6, Dr Jacobi was the guest of honor at a testimonial dinner given by the New York Yacht Club at which were present more than twenty physicians who have acted as his assistant in the hospital and college in which he has worked

Baby Week.—The week of May 6 to 12 was Baby Week in this city and in this connection infant mortality studies have been made by Registrar Guilfoy of the department of health which reveal the very remarkable fact that the death rate from congenital defects is greater among babies of the rich than among babies of the poor The infant mortality rate for the whole city, based on 141,256 births reported during the year, was 98 per 1,000 In several of the better districts of the city only 25 to 50 per 100 die in the first year of life, while in a district inhabited largely by negroes and Italians, 314 babies out of every 1,000 died during the first year of life The death rate from infectious and diarrheal diseases in nearly all the so-called well-to-do districts is far below the average for the city In all districts where the colored population represented at least 10 per cent of the entire population the rates varied from 124 to 314 per 1,000 The reason for the preponderance of deaths from congenital causes among the well-to-do is to be further studied Dr Bolduan has suggested that the later age at which people of this class marry may prove to be the deciding factor

OKLAHOMA

Inspection of Schoolchildren—The state board of health has recently examined 4,000 schoolchildren in Kiowa, Roger Mills and Washita counties and has found that 15 per cent have defective sight, 12 per cent defective hearing, 25 per cent nasal trouble, and 35 per cent defective teeth

Personal—Dr Walter Penquite, Chickasha, is spending the spring in San Angelo, Texas, on account of his health——Dr Edwin W Van Brunt, Watonga, has been appointed health officer of Blaine County——Dr Charles W Bacon, Yale, fractured both bones of the right forearm while cranking his automobile recently——Dr McDonald Looney, Burneyville, who was recently injured by the falling of a horse which he was riding, is convalescent

PENNSYLVANIA

Insane Patients to Pay—Reversing the Delaware County Court in three lunatic support cases, Justice Potter of the Supreme Court filed opinions clearing the way for the state to obtain reimbursement of thousands of dollars for the support and maintenance in the state hospitals of mentally afflicted persons who were admitted as 'indigent" but who had estates at the time or who received inheritances subsequently

Personal.—Dr Milton C Dunnick, Shrewsbury, is convalescent after an operation for appendicitis which he underwent recently at the West Side Sanitarium York——Dr George W Harrington, Hazleton, was seriously injured by a fall down stairs, May 2——Dr D E Sable, chief of police and fire surgeon of Pittsburgh, was seized with appendicitis, May 4, and removed to the South Side Hospital where operation was performed——Dr Malcolm C Grow, Media arrived in New York, May 11, after four months' service as surgeon with the Russian army Dr Grow has been decorated with the Cross of St George for bravery and intends to spend seven weeks in this country, and to purchase medical supplies before returning——Dr Louis J Burns Philadelphia has been appointed laryngologist to St Mary's Hospital——Dr James M Torrance of the Hospital for Contagious Diseases has been appointed second assistant physician of that institution——Dr Krusen of the Department of Health and Charities has announced three appointments Dr Robert G Torrey to succeed Dr William Pepper as visiting physician to the Philadelphia General Hospital, Dr E. J G Beardsley as visiting physician to the Tuberculosis Department of the Philadelphia General Hospital, and Dr Theodore T Melnick to be intern at the Philadelphia Hospital for Contagious Diseases

Philadelphia

Hospital Items—A $75000 Lincoln Memorial Building is planned for the Mercy Hospital——The Friends' Hospital Frankford is turning over 900 acres of woodland at Fox Chase to the State Forestry Department as a Forest Reserve The hospital managers will plant 16,000 trees this year, the state furnishing the saplings

Health Education Experiment—Health Director Krusen has announced that an experimental health district is to be established in South Philadelphia so that the plan of health education may be given a thorough trial under municipal direction The district will be under the supervision of Dr Krusen and his assistants and the work to be done will be the intensive education of the people in matters of health and hygiene

Today and Tomorrow Exhibit—The West Philadelphia Hospital for Women the only one west of the Schuylkill River which is operated exclusively for women will have an exhibit at the Philadelphia Today and Tomorrow Exhibition held in the Commercial Museum Building May 15 to June 10, showing the maternity work done in 1889, when the hospital started and what is being done today by its staff of women physicians The hospital has just broken ground for a new $75000 Maternity Building in connection with its present equipment

Conference of Teachers of Blind—A two-days conference of teachers of the blind was held, May 11 and 12 under the auspices of the Pennsylvania Institution for the Instruction of the Blind Members from Delaware, New Jersey and Maryland were present The majority of the teachers themselves were sightless The conference proceedings were in charge of Mr Maloney, of the Pittsburgh Institute for the Blind and Dr L Webster Fox, of Philadelphia, president of the society The problem of what to do with children of the Twilight Zone" was discussed, as education of blind children in public schools is not compulsory and the many children who can see a little have no means of getting an education for the Pennsylvania schools for the blind do not take children who have more than one tenth of the normal vision owing to the lack of room

SOUTH DAKOTA

State Medical Society Meeting—The annual meeting of the South Dakota State Medical Association will be held in Aberdeen May 23 to 25 under the presidency of Dr James B Vaughn, Castlewood, with headquarters at the Elk s Club

Honor State Hospital Superintendent.—In honor of the twenty-fifth anniversary of the superintendency of Dr Leonard C Mead of the State Hospital for the Insane, Yankton, 120 members of the Eighth District Medical Society and other guests assembled at a banquet in the new women s building of the hospital to pay tribute to Dr Mead A number of eulogistic addresses were delivered and a handsome loving cup was presented by the society to Dr Mead

CANADA

Hospital News.—Western University, London, Ont, is organizing a stationary hospital for overseas service Dr Edwin Seaborn is commanding officer with the rank of lieutenant-colonel Dr Clarence E Brown, London, is senior major, and Dr John Cameron, Wilson, who has just returned from France, is junior major The captains are Drs James Moriarty, Mimico, and Dr Ernest H Young, Kingston

University of Toronto Base Hospital—The report that this hospital was to be moved to France proves incorrect The hospital will remain at Saloniki for some time to come Its position, however, has been changed It is now on the east side of Saloniki, 10 miles from its former position, and is situated on a promontory of land with a bay on each side This hospital is said to have done magnificent work, as have the other Canadian hospitals

Personal—Col Murray MacLaren, M D St John, N B, Commanding Officer of No 1 Canadian General Hospital has been appointed deputy director of the Canadian Medical Services——Dr Walter S Verral, Vancouver, M C, has been appointed superintendent of the Toronto Orthopedic Hospital in succession to the late Dr B E Mackenzie——Capt S G Chown, Winnipeg, Man, has been appointed Advance Department Medical Officer in France——Dr G Stirling Ryerson Toronto, has resigned the presidency of the Canadian Red Cross Society

Untrained Midwives in Toronto—Dr Edmund E King, vice president of the Ontario Medical Council, and a member of the Council of the Academy of Medicine, Toronto, addressed the medical commission on behalf of these bodies recently with regard to the proposal to license midwives in Ontario Dr King told the commissioner that there were no licensed midwives in Ontario and that it was a dangerous thing for mother and babe to have an untrained woman in attendance on them He further said that untrained women did much work among the foreign population in Toronto with unfortunate results The opinion seems to prevail among practitioners in Ontario that if midwives are to be licensed that an act should be framed so as to copy the act now in force in Great Britain

GENERAL

Correction—The general superintendent of the Medical Department of the United Fruit Company writes that the obituary notice of Dr Francis T B Fest, which appeared in The Journal of April 8, was incorrect in two particulars Dr Fest had been an assistant surgeon in the service of the United Fruit Company and had resigned from the service in December 1913

Pharmacopeia Adopts Metric System.—The revised edition of the United States Pharmacopeia, now in preparation, will make exclusive use of the metric system and in order to aid in its transition, the United States Bureau of Standards has prepared a circular on weights and measures for pharmacist and physician The bureau has also furnished the committee on revision of the Pharmacopeia with definitions of the several degrees of fineness of drug powders and methods to be used in their determination

Immunologists Convene—At the third annual meeting of the American Association of Immunologists held in Washington D C May 11 and 12 under the presidency of Dr James W Jobling Nashville, Tenn, Dr Richard Weil, New York, was elected president, Dr John A Kolmer, Philadelphia, vice president, Dr Martin J Synott, Montclair, N J., secretary (reelected), Dr Willard J N Stone, Toledo, Ohio treasurer (reelected), and Drs William H Park New York, and Arthur F Coca, Flushing, L I, were elected councilors

Conference of U S Public Health Service with State Health Officers—The fourteenth annual conference of the U S Public Health Service with state and territorial health authorities was held in Washington on May 13 and 15 Representatives of twenty-three states and territories were present Among the more important topics discussed were uniformity of interstate and intrastate regulations for the prevention of the spread of communicable diseases through common carriers, the collation and use of morbidity reports, and health insurance

Throat, Nose and Ear Men Elect—At the annual meeting of the American Laryngological, Rhinological and Otological Society, held in White Sulphur Springs, W Va., May

5 and 6, under the presidency of Dr Seth M Smith, Philadelphia, the following officers were elected president, Dr Thomas J Harris, New York, vice presidents, Drs John F Culp, Harrisburg, Pa, John E Brown, Columbus, Ohio, Richmond McKinney, Memphis, Tenn, and James A Patterson, Colorado Springs, Colo, secretary, Dr William H Haskin, New York, and treasurer, Dr Ewing W Day, Pittsburgh

Conference of State and Provincial Boards of Health—The annual conference of secretaries of state and provincial boards of health was held in Washington on May 16 This is a voluntary association of the health agencies of the several states of the United States and of the provinces of Canada In that respect it differs from the annual conference of the health agencies of the states and territories with the United States Public Health Service, referred to elsewhere in this issue, which is a strictly official organization, created by the law under which the Public Health Service is now organized

Community *Experiment on Tuberculosis*—The National Association for the Study and Prevention of Tuberculosis has been presented with $100,000 by the Metropolitan Life Insurance Company to demonstrate by a community experiment, for three years, that tuberculosis can be controlled as any other infectious disease, if right methods and adequate resources are available It is planned to select a town or ty of about 5,000 inhabitants, probably in New York or Massachusetts, and to apply there all the knowledge and treatment of tuberculosis available with a view to the ultimate eradication of the disease

U S P H Service Personal—Senior Surgeon Fairfax Irwin began a month's tour of inspection of the coast guard service along the New Jersey coast on May 5——Senior Surgeon Charles E Banks has been appointed sanitary inspector and medical officer in charge of the United States Safety First special train which is now making an educational tour of the country carrying hundreds of exhibits illustrative of the methods employed by the federal government for saving human life and property, both at sea and on land——S A Surg Joseph R. Ridlon, Savannah, has been placed temporarily in charge of the work of Dr D B Moss, state bacteriologist of Alabama, Montgomery

Bequests and Donations—The following bequests and donations have recently been announced

Eaglesville (Pa) Sanatorium for Consumptives, $6,000, the receipts from a benefit performance at a Philadelphia theater, April 27

Camden (N J) Municipal Hospital, an appropriation of $8,000, by councils, for furnishing and equipment.

Philadelphia Home for Incurables, $2,000, by the will of Elizabeth M Henderson

Philadelphia Orthopedic Hospital, Presbyterian Hospital and Hospital of the University of Pennsylvania, Philadelphia, each $15 000, for the establishment of free beds in memory of Henry Davis, Mary S B Davis and Mary Davis Tenbrook, the Hospital of the University of Pennsylvania to use the income for aiding worthy students, preferably residents of Maine, Philadelphia Home for Incurables, $1,000, by the will of *Mary D Tenbrook*

Louisiana Methodist Orphanage, Ruston, a donation of $5,000, by Dr Luther Sexton, New Orleans

Associated Jewish Charities of Chicago, twelve thirtieths, Alexian Brothers Hospital, Chicago, Jewish Orphan Asylum, Cleveland, German Old Peoples Home, Forest Park, Home for Jewish Friendless and Working Girls, and Chicago Home for the Friendless each one thirtieth, Chicago Home for Jewish Orphans, and Chicago Winfield Tuberculosis Sanatorium, each two thirtieths, Jewish Training School, Jewish Aid Society for Relief, and Home for Aged Jews, Chicago, each two thirtieths, of the income of the estate of Hyman Lowy, appraised at $300,000, *twenty one* years after the death of the last grandchild now alive

Presbyterian Hospital, New York, $100,000, by the will of Charles W Harkness

Massachusetts Medical Benefit Society, $1,000, and Dr John W Pratt, Dedham, $500, by the will of Virginia Carpenter, Dedham

Temple University, Philadelphia, $2,000, by the will of Adeline Winters

Hahnemann Hospital, Philadelphia, $12,000, by the will of Isabella T McQuade

Wills Eye Hospital, Philadelphia, a contingent bequest of $2,250, by the will of Eloise King

Wine of Cardui Suit—Since the publication of the last item concerning this suit (The Journal, May 13, 1916, p 1560), following the testimony of Dr Torald Sollmann, there were called to the stand for the defendant—the Association—Dr Paul N Leech, *Dr Lewis E Warren* and Dr Arthur J Cramp, who identified specimens and connected up points in the testimony for the defendant There were then introduced into evidence various exhibits for the defendant Mr E A Wheatley, advertising counsel for the Chattanooga Medicine Co, was asked concerning the billboard advertisements used by the Chattanooga Medicine Co Mr Hough admitted, on behalf of *the plaintiff*, without conceding that it was an issue in the case, that Wine of Cardui was advertised as extensively as possible There was then called to the stand Dr W S Leathers Before this witness' evidence was taken the Court intimated that it was disposed at *this point* to limit further expert evidence After some discussion, the defendants rested their case Mr Hough stated that at this stage of the trial it was proper to inquire to what extent the defendant has justified, in other words, whether any evidence has been produced *which would* justify the jury in returning a verdict The Court stated if the defendants have not justified as to everything then there is something where the jury must find a verdict Argument was made on this question and the Court finally stated that he would let the case go to the jury

There were then called as witnesses for the plaintiff up to the time of going to press, Dr Francis P Mason, chemical engineer, Dr George W Funck, Dr Francis E Thornton, Dr Albert F von Zelinski *and Dr George C Amerson*, Chicago There were also read numerous depositions from various women who had used Wine of Cardui

Medical Museums—The ninth meeting of the American Section of the International Association of Medical Museums took place at the Army Medical School, Washington, D C, May 8 Dr Aldred S Warthin, Ann Arbor, Mich, was in the chair, and the following officers were elected president, Dr Oskar Klotz, Pittsburgh, vice presidents, Drs W M Late Coplin, Philadelphia, H E Robertson, Minneapolis, and Daniel S Lamb, Washington, D C, councilors, Dr Aldred S Warthin, Ann Arbor, Mich, W M Late Coplin, Philadelphia, Howard T Karsner, Cleveland, Milton C Winternitz, Baltimore, and Robert A Lambert, New York, secretary-treasurer, Dr Maude E Abbott, Montreal, and assistant secretaries, Drs Joseph Kaufmann and William W Francis, Montreal An important discussion took place on the standardization of square glass museum jars and the problem of *obtaining a source of supply of these* under existing war conditions It was decided to simplify the problem by reducing the large number of miscellaneous sizes, now in use among museums, to from 11 to 16 sizes and a committee was appointed, consisting of Drs Klotz, Winternitz and Abbott, whose business it should be to approach local glass manufacturers on the one hand and members of the American Section of the Museums Associations on the other and thus attempt to secure a supply of the selected sizes, which it was felt *should be obtainable* in this country as soon as the large demand which exists becomes definitely formulated A fine series of exhibits was on view from the Army Medical Museum, Washington University Medical School, McGill Medical Museum, Montreal, and various members of the American Association of Pathologists and Bacteriologists This exhibiton remained open during the three days of the congress

FOREIGN

Pathologic Professorship Endowed—In the will of the late Mr Stanley Bode, who left an estate valued at about $160,000, after providing for certain legacies, the residue of the property was left in trust for his mother and sister and to the survivor of them and subject thereto, a bequest of $10,500 to Epsom College for one foundation scholarship and the ultimate residue to the University of London for the endowment of professorship in pathology in the Medical School of Charing Cross Hospital Of the property bequeathed to him by his wife, he gives, in addition to the number of legacies to her relatives, $5,000 each to the London School of Medicine for Women, the New Hospital for Women, and the pathologic department of the New Hospital for Women, and any residue to the New Hospital for Women

New American Hospital in Panama—The new buildings of the Colon Hospital have been completed and turned over to the United States medical authorities for Colon Cristobal The patients will be transferred from the old quarters this month and the old wooden *structures* will be removed The new hospital will then have an unbroken sea front and full advantage of the prevalent ocean breezes The buildings are four in number, of reinforced concrete with tile roof, arranged on the pavilion plan, with an administration building in the center, an east wing for wards and a west wing for dispensary and private rooms and a service building in the rear There are also an emergency ward, laboratories Roentgen-ray room, dark room and all other modern hospital conveniences The buildings are thoroughly screened have ample protecting verandas the entire length of the building and an enclosed sun porch at the end

Protest Against British Holding up Supplies—The chairman of the Central Committee of the American Red Cross has forwarded a letter to the secretary of state, dated May 8, in which he submits the facts that since the beginning of the present war the American Red Cross has invited contributions of money and supplies for the wounded and sick of all belligerent powers, that it has shipped to these powers the supplies contributed, that it has had no difficulty in sending such articles to the entente allies, but that since September 1915 there has been delay in granting permits by Great Britain for shipment by the American Red Cross to the central powers Since January of this year only one permit has been granted The Red Cross is now in receipt of a communication from the state department enclosing a dispatch from the British government in which it definitely withdraws its consent for the shipment of such articles by the American Red Cross and this in effect announces its purpose to treat them as contraband of war As the American Red Cross considers it to be in the interest of the humane conduct of wars that the principles of the Geneva Convention shall obtain it urges on the state department the propriety and wisdom of directing the matter again to the British government with the hope that it may change the attitude maintained by it, which appears to be based on a misconception of the attitude of the central powers in respect to Article 29 of the Declaration of London This article provides that articles serving exclusively to aid the sick and wounded shall not be treated as contraband of war

LONDON LETTER

London, May 1, 1916

The War

THE HEALTH OF THE BRITISH EXPEDITIONARY FORCE IN FRANCE

As stated in previous letters the health of the soldiers thanks to protective precautions has been remarkably good Typhoid fever which caused 8 000 deaths in South Africa has been almost absent The greatest precautions are taken against carriers, no soldier who contracts the disease is allowed to mix with others till he has satisfied the bacteriologists that he is free from the bacilli and even the civilians in the villages in the war zone are examined bacteriologically, and if found to be carriers are removed This work is done in laboratories which at first were mobile but now are stationary There are fourteen in which about 2,000 samples are examined weekly

NERVOUS DISORDERS

Nervous disorders due to the shock and strain of bombardment are conditions which cannot be affected by hygienic precautions With the modern development of big guns and high explosives, shell shock has become frequent A committee has been appointed to investigate the subject in cooperation with the leading French neurologists The cases have shown great divergence from the disorders observed in civil life When exposed to concussion of a high explosive, a variety of symptoms may be produced All consciousness of the explosion may be obliterated, or the soldier may simply become dazed and afterward his conduct may be 'curious" and his actions indeterminate For these conditions the only treatment is rest After a heavy bombardment a healthy man may break down, and if removed to a place of safety collapse and fall asleep in spite of the noise that is going on Some men then recover, but others cannot support noise for a long time They show overreaction to noise A cab whistle or an exploding tire outside a convalescent home will bring some patients from their beds In another group a condition of nervous irritability rather than exhaustion is produced Thus continuous shelling, even though it produces few casualties has a wearing down effect In men with a stable nervous system the effect is temporary but it is not so in those with neurotic tendencies Hence our neurologists who are familiar with the nervous systems of our men and our enemies predict that the imperturbable British temperament will confer an advantage in the coming struggle

THE EFFECTS OF THE WAR ON THE MEDICAL PROFESSION

The results achieved by the Central Medical War Committee of the profession in organizing a medical service for the greatly expanded new army are gratifying We have reached a stage of preparedness, and are ready for any measures the government may consider necessary Most of the physicians now remaining in civil practice are married men, and many of these have enrolled for service If a measure of compulsion should prove necessary, the profession will offer no opposition Indeed, the number of men who can thus be obtained cannot now be considerable.

DEARER DRUGS

In The Journal, Jan 29, 1916, p 368, was a table showing a great increase in the cost of drugs since the outbreak of war The following more recent list shows how many times dearer the most commonly used drugs are It contains some new items and also shows a diminution in some cases and an increase in others of the cost

NUMBER OF TIMES THE PRICES OF DRUGS HAVE INCREASED OVER THE PRICE AT OUTBREAK OF WAR

Drugs	Times	Drugs	Times
Acetanilid	11	Phenol (carbolic acid)	6
Acetphenetidin (phenacetin)	26	Potassium bromid	16
Acetylsalicylic acid	25	Potassium chlorate	7
Antipyrin	12	Potassium permanganate	27
Caffein	3½	Quinin	3
Calomel	2¼	Salicylic acid	20
Citric acid	2	Sulphonal	5
Cocain	7½	Tartaric acid	3¼
Cod liver oil	11	Thymol	3½
Cream of tartar	2	Veronal	3

The most remarkable advance is in the case of potassium permanganate, which used to be sold at the rate of 40 shillings a hundredweight Now it is quoted on the wholesale market at 10 shillings a pound, and dealers who used to traffic in ton lots are glad to pick up a few pounds here and there from retail pharmacists

THE WORK OF BRITISH ARMY SURGEONS FOR FRENCH CIVILIANS

In a previous letter, reference was made to the work done by British Army surgeons among the French civilians in the area occupied by our troops Deprived by mobilization of their ordinary medical advisers, the French population would in many cases be unable to obtain advice but for British help which is gladly and freely given and has evoked expressions of gratitude from the French authorities Moreover, a considerable amount of drugs and dressings has been supplied This service has been organized in various ways In some cases individual medical officers are told off for civilian duty in rotation a month at a time In other cases it is caused to be generally known that two will be in attendance to receive civilian patients during a specified hour of the day In not a few instances, when an epidemic of typhoid or other disease has been suspected, very vigorous sanitary work has been prosecuted over a given district, and there is no doubt that more than one epidemic has been successfully averted Besides ordinary illnesses there are, of course, casualties among civilians as a result of shelling One class of work rather foreign to their ordinary vocation, which the physicians have had regularly to do in the absence of the usual practitioners, is midwifery The gratitude for the work done is marked, cases being recorded of fees after the usual refusal to accept them, being anonymously deposited in officers' billets at night when it has been impossible to trace their origin No less pleasant, perhaps, is the fact that no official records have been kept of the work done As one officer, apologizing for not being able to give accurate figures, phrases it, "It seemed so natural to do it that it was hardly thought of" And this has been almost universal One army, indeed is able to report that the average number of civilian cases treated has been about 245 a day Another can testify to 463 major operations performed of which there would necessarily be records and estimates about 16 000 cases in all Much good work has also been done in helping the poorer sections of the people Subscriptions in special cases have been made on the spot and in other instances money has been raised for local needs by appeals in England A certain medical officer has been so active in connection with a children s hospital that he is known in the neighborhood as 'English Papa"

The Neglect of Science by the Government

At the Royal Institution H E Armstrong, the chemist, recently delivered a lecture on Organic Products Used in Medicine. In referring to the results obtained through the feverish activity of German laboratories in the production of artificial drugs he said they were based on hydrocarbon originally obtained by our Faraday as a by-product of oil gas He pointed out that benzene the foundation stone of the organic chemical industry, was discovered and defined in that institution ninety years ago Through Faraday's pioneer work the light hydrocarbons of coal tar were investigated at the College of Chemistry in 1846 Ten years later the first artificial dye was discovered and manufactured, and a perfume was also artificially made near Harrow The connection between chemical constitution and physiologic action was first brought into prominence in Edinburgh Abel developed the gun cotton industry into a stable existence in the sixties, and its application in conjunction with nitroglycerin to military purposes resulted from the work of Abel and Dewar Why, after having done so much, had we allowed ourselves to fall behind? If we were not to get what we wanted from Germany after the war, we must, as the Australian prime minister had said, attack the problem systematically and scientifically The universities and public schools placed so high a premium on classical studies that ability was attracted away from science With no regular remunerative outlet for science, few took it up, and workers found opportunity in industry The Royal Society had become ıc preserve of the academic worker, consequently it had been reduced to impotence, and no sufficient use was made of its great resources Though 999 out of every 1,000 suggestions brought before the Inventions Committee were useless, as Mr Balfour had stated, distinguished scientific men were wasting their time on such committees, and the country was misled into supposing that it was receiving the help of science The casual inventor has been considered, but not those who could give efficient assistance It was not that science was unable to help, it was simply not allowed to It was, however useless to complain of government apathy and of public ignorance as to the application of science to industry, when the body scientific itself remained unorganized Science, he feared, was losing rather than gaining ground in this country Through being ineffective collectively, science was voiceless in the councils of the nation

BERLIN LETTER

Berlin, April 18, 1916

Personal

Professor Hofmann, director of the physiologic institute at Konigsberg, has succeeded to the position held by Professor Schenck in Marburg

Prof A Wolff, director of the dermatologic clinic in Strassburg, died, aged 65 years In addition to a textbook on skin and venereal diseases, Wolff has written much on the heredity of syphilis and on gonorrhea in women

The successor to Professor Plehn, recently called to Berlin, is Professor Jurgens, formerly director of the medical division of the New Cologne city hospital

The Feeding Problem

In order to facilitate the problem of feeding the poor, several of the suburbs of Berlin have provided transportable kitchens These kitchens, popularly termed "goulash cannons" are driven through the poor parts of the cities and a good noonday meal is furnished at the rate of 35 Pfennige (8 cents) per liter (quart) This meal consists of vegetable soup cooked with potatoes and meat

The Future of Disabled Soldiers

Every effort is being made to lessen the difficulties confronting the invalid by providing suitable occupation for him and also encouraging him in taking up a homestead, thus insuring permanent citizenship The government recently proposed to the Reichstag that there be enacted a law which would make it possible to advance a certain sum of money to those injured in the war This will encourage these
persons to buy homes, and fro cal and sanitary
points of view much is to be ic wel-
fare It will make it possibl to
observe proper sanitation and
sion has repeatedly pointed o
tuberculosis, and the mortality of
homes must be provided The loan
proposes to make is available to all inv
of 21 and 55 who propose to use money
approved purpose A civil as well as a me
will be made Furthermore, such applicants w
any pensions unless their earning capacity has
ished at least 0 per cent by their invalidism T
loan will be giv to invalids who are not more than
of age Such a oan will be sixteen times greater t
war pension, that is, 2,880 marks ($720) It will dir
with age so that the invalid of 55 will receive the smallest sum, seven and one-half times the war pension Each applicant will be permitted to capitalize his field allowance and "mutilation" allowance so that a man aged 29 who has lost his right hand may be given a loan of 7,056 marks ($1,764)

Cooperation Between Chemistry and Biology

Emil Fischer, a chemist of Berlin, recently delivered an address on organic synthesis which portrayed a rather hopeful state of affairs for future cooperation between chemistry and biology His concluding remarks were as follows "Biology has profited much from the chemical examination of the purins It is known that the purin of nucleinic acid in man furnishes the material from which uric acid is made If the amount of uric acid becomes large, or if for other reasons the excretion of uric acid is interfered with, then, because of its very slight solubility, it is deposited in the joints, in the urinary bladder, kidneys, blood vessels, heart muscle, etc, and causes gout, kidney and bladder stones Such patients are today given a diet containing very little nucleoprotein, and every effort is made to administer substances which will increase the solubility of the uric acid and further its excretion from the body On the other hand, debilitated patients will be given nucleinic acid The decomposition products of nucleinic acid—sugar, purin bodies and phosphoric acid—may be produced synthetically Why not then make nucleinic acid synthetically? This has, in fact, already been done, and a sample is at hand of a synthetic nucleinic acid which is even crystallizable (theophyllinglukosidphosphorsäure) The war has stopped further research in this direction, but the work done thus far shows what can be accomplished by synthesis Other substances, doubtless, will be produced in a similar manner, and it is to be expected that before many years have elapsed the chapter on synthesis of nucleinic acid will be as extensive as that on carbohydrates, fats and purins No one will doubt that biology
will derive much benefit from these chemical r es
because they bear directly on metabolism and sin

Association News

THE DETROIT SESSION

Boat Trips to the Convention City

The local Committee on Arrangements calls the attention of the Fellows of the Association to the delights of a boat trip to Detroit. It is suggested that other cities follow the example of Chicago and charter passenger boats for a lake trip to Detroit, retaining the boats in Detroit as floating hotels during the meeting. It has been done on previous occasions in that city, and has helped out hotels in somewhat relieving congestion.

While the hotels of Detroit have ample accommodations for large meetings such as that of the American Medical Association, the advance reservations have poured in so rapidly that in order to insure every one satisfactory accommodations, the local committee recommends that those who enjoy a boat trip shall come to Detroit by boat and occupy their staterooms during the meeting.

Deaths

Thompson Elbridge Potter, M.D., St. Joseph, Mo.; Jefferson Medical College, 1875; aged 66; a Fellow of the American Medical Association; professor of physiology and diseases of the nervous system in Northwestern Medical College, St. Joseph; one of the founders of Central Medical College and professor of surgery and president of the institution, and on the merger of Central and Ensworth Medical Colleges in 1905, he became professor of principles and practice of surgery and secretary of Ensworth Medical College, St. Joseph; surgeon to St. Joseph's and the Ensworth hospitals; from 1882 to 1886 local surgeon of the Hannibal and St. Joseph Railroad at Cameron, Mo., and mayor of that city in 1884-1885; founder in 1880 and for several years editor of the *Western Medical and Surgical Reporter*; died at his home, April 29, from nephritis.

Frederick Townsend, M.D., Sault Ste. Marie, Mich.; New York University, New York City, 1894; aged 47; acting assistant surgeon, U. S. P. H. S.; a Fellow of the American Medical Association and American College of Surgeons; formerly professor of anatomy in the Detroit College of Medicine; assistant surgeon to the Upper Peninsula State Hospital, Newberry, and in charge of the local work of the United States Public Health Service at Sault Ste. Marie and examining surgeon for the immigration department; local surgeon for the Duluth, South Shore and Atlantic and Minneapolis, St. Paul and Sault Ste. Marie railways and the Trans-Ste. Marie Traction Company; died at his home, April 26, from pneumonia.

Amos P. Dodge, M.D., Oneida, N. Y.; University of Maryland, Baltimore, 1874; aged 62; a Fellow of the American Medical Association and once vice president of the Fifth District Branch of the Medical Society of the State of New York; a charter member of the New York and New England Association of Railway Surgeons and of the Oneida Medical Club; for four years health officer of Oneida and for thirty years division surgeon of the New York Central Lines and the West Shore system; died at the home of his daughter in Oneida, May 3.

Elbert Wing, M.D., Los Angeles; Northwestern University Medical School, 1882; aged 63; a Fellow of the American Medical Association; for several years professor of nervous diseases and medical jurisprudence in his alma mater, and attending neurologist to St. Luke's and Provident hospitals, who moved to California in 1904 on account of ill health; vice president of the Sewell-Clapp Envelope Company; died at home, May 8, from cerebral hemorrhage.

William Howard McKenzie, M.D., Newark, N. J.; College of Physicians and Surgeons in the City of New York, 1892; aged 48; a member of the Medical Society of New Jersey; physician of Essex County for more than ten years and president of the medical board of St. Barnabas' Hospital, Newark, was seized with a cerebral hemorrhage while attending a meeting of the board and died a few hours later in the institution.

Charles Frederick Osgood, M.D., Ogden, Utah; Rush Medical College, 1890; aged 48; a Fellow of the American Medical Association and a prominent practitioner of Utah; a member of the Board of Medical Examiners of the State of Utah; a specialist on diseases of the ear, nose and throat, was shot and instantly killed in his automobile, May 2, by a man supposed to have been of unsound mind.

Robert B. Turner, M.D., Waco, Texas; Medical College of Ohio, Cincinnati, 1874; aged 65; formerly a member of the State Medical Association of Texas; chairman of the McLennan County Lunacy Board since 1913, was found dead in his office, May 2, from a gunshot wound of the head believed to have been self-inflicted, with suicidal intent while despondent on account of ill health.

John Davidson Jones, M.D., Cleveland; Western Reserve University, Cleveland, 1866; aged 78; a Fellow of the American Medical Association; for ten years a member of the Board of Education of Newburg, Cleveland, and for ten years thereafter a member of the Cleveland board; died in the Charity Hospital, Cleveland, May 4, four weeks after a surgical operation.

William Henry Sledge, M.D., Mobile, Ala.; University of Mobile, Ala., 1881; aged 60; formerly a Fellow of the American Medical Association; a member of the Medical Association of the State of Alabama and once president of the Mobile County Medical Society; for thirteen years president of the Board of Education of Mobile County; died at his home, April 30.

Francis Besant Bishop, M.D., Washington, D. C.; University of Maryland, Baltimore, 1883; aged 62; a Fellow of the American Medical Association and formerly president of the Medical and Surgical Society of the District of Columbia and of the American Electro-Therapeutic Association; died at his home, April 30, from meningitis following mastoid abscess.

Jesse Edwards Hunt, M.D., Kansas City, Mo.; Western Reserve University, Cleveland, 1902; aged 37; formerly a Fellow of the American Medical Association; a member of the Missouri State Medical Association; professor of pediatrics in the University of Kansas and a member of the staff of Mercy Hospital; died at his home, April 29, from diphtheria.

Burwell Alexander Duncan, M.D., Morehouse, Mo.; Medical College of the State of South Carolina, Charleston, 1857; aged 80; a Fellow of the American Medical Association; an esteemed practitioner of Aberdeen and Columbus, Miss., until 1902, when he located at Morehouse; died at his home, April 14, from cerebral hemorrhage.

John Gibson, M.D., St. Albans, Vt.; University of Vermont, Burlington, 1898; aged 48; a member of the Vermont State Medical Society; formerly adjunct professor of materia medica and therapeutics in his alma mater; a member of the medical staff of St. Albans Hospital; died suddenly at his home, May 3, from heart disease.

George Augustus Quimby, M.D., New York City; New York University, New York City, 1857; aged 84; said to have been the oldest alumnus of his alma mater; surgeon on the staff of the New York Hospital in 1856 and a member of the staff of St. Luke's Hospital from 1865 to 1867; died at his home, May 3.

Adolph G. Beyer, M.D., Milwaukee; Milwaukee Medical College, 1909; aged 45; formerly a Fellow of the American Medical Association; at one time a member of the faculty of the Wisconsin College of Physicians and Surgeons; died in the Emergency Hospital, Milwaukee, April 29, from pleuropneumonia.

Albert S. J. Burchett, M.D., Memphis, Tenn.; Meharry Medical College, Nashville, Tenn., 1884; aged 55; a colored practitioner, was found dead in Wills Park, Memphis, April 29, from a gunshot wound believed to have been self-inflicted with suicidal intent while despondent on account of business affairs.

Alexander H. Hepburn, M.D., Chicago; Northwestern University Medical School, 1899; aged 41; a member of the Illinois State Medical Society and a veteran of the war with Spain, in which he served as a member of the First Illinois Cavalry, U. S. V.; died suddenly, May 9, from diphtheria.

William Stanford Stevens, M.D., Boston and St. Albans, Vt.; Harvard Medical School, 1883; aged 56; in 1891 a member of the Massachusetts Legislature and in 1888 and 1889 a member of the Common Council of Boston; died at his home in Boston, April 29, from myocarditis.

Charles Poplin Harvielle, M.D., Salt Lake City; Washington University, St. Louis, 1899; aged 40; a Fellow of the

American Medical Association, assistant county physician of Salt Lake County, who had suffered for several years from disease of the throat, died in Denver, May 2

George Augustus Fagan, M D, North Adams, Mass, McGill University, Montreal, 1898, aged 45, a member of the staff of the North Adams Hospital and chairman of the North Adams Board of Health, died in the Samaritan Hospital, Troy, N Y, April 1, from Pott's disease.

Albert O Ward, M D, Indianapolis, Medical College of Indiana, Indianapolis, 1874, aged 73, for forty-nine years a practitioner of Indianapolis, a Fellow of the American Medical Association and a veteran of the Civil War, died at his home, May 1, from myocarditis

Edward Mortimer Paterson, M D, Oakland, Calif, Harvard Medical School 1871, aged 71, formerly professor of physiology and histology in the College of Physicians and Surgeons, San Francisco, died at the home of his son in San Jose Calif April 24

Buel Smith Bigelow, M D, Chicago, University of Vermont, Burlington, 1863, aged 76, died in the Henrotin Memorial Hospital, Chicago, April 24, from cancer of the cecum for the relief of which an operation had been performed a few days before

Herbert Stanley Monkman, M D, Vegreville, Alta, Trinity Medical College, Toronto, 1906, aged 39, at one time a practitioner of Bottineau, N D, captain in the Third Canadian Mounted Rifles, was killed in battle "somewhere in Flanders," December 2

Millard Fillmore Crawford, M D, Wray Colo, College of Physicians and Surgeons Keokuk, Ia, 1878, aged 60, for several years a practitioner of Yuma, Colo, for a month before his death a resident of Wray, died May 2, from influenza

Felix Amabile, M D, New York City, New York University, New York City, 1884, aged 54, died in his office, May 8, from the effects of hydrocyanic acid, self-administered, it is believed with suicidal intent while despondent on account of ill health

William Henry Harrison Warman, M D, Washington, D C, Howard University, Washington, 1880, aged 75, a medical examiner in the United States Pension Office, Washington, died at his home, April 17, from cerebral hemorrhage

Maurice Feiman, M D, Canton, Ohio, Cleveland College of Physicians and Surgeons, 1910, aged 27, formerly a Fellow of the American Medical Association, who was taken ill in Switzerland two years ago, died in Silver City, N M, May 2

John J Mugan, M D, North Battleford, Sask, formerly of Langdon, N D, Manitoba Medical College, Winnipeg, 1906, aged 46, formerly a Fellow of the American Medical Association, died at his home, February 5, from nephritis

John Erle Kenney, M D, Cheslea, Mass; University of Burlington Vt, 1882, aged 54, formerly a Fellow of the American Medical Association, a member of the Massachusetts Medical Society, died at his home, May 3

Ernest Clifton Morris, M D, Hephzibah, Ga, Medical College of Georgia, Augusta, 1899, aged 36, formerly a Fellow of the American Medical Association, died at the home of his father-in-law near Hephzibah, April 28

John A Hunter, M D, Philadelphia, University of Pennsylvania, Philadelphia, 1866, aged 78, formerly an assistant in his alma mater and visiting physician to Moyamensing Prison, died at his home, April 29

William H Yelton, M D, Butler, Ky, Cincinnati College of Medicine and Surgery, 1869, aged 72, a member of the Kentucky State Medical Association, died at his home, January 18, from cirrhosis of the liver

Axel Fridolf Swanson, M D, Southampton, Mass, Albany (N Y) Medical College, 1913, aged 24, a member of the Massachusetts Medical Society, died at his home, March 19, from pulmonary tuberculosis

C J Renfro, M D, North Pleasureville, Ky, Jefferson Medical College, 1867, aged 73, a Confederate veteran, formerly a Fellow of the American Medical Association, died at his home, recently

George Lane Fenton, M D, Kingsley, Mich, Eclectic Medical Institute, Cincinnati, 1893, aged 67, a member of the Michigan State Medical Society, died at his home, April 29, from pneumonia

Barton M Fletcher, Middlesboro, Ky (license, Tennessee, 1889), aged 79, a Confederate veteran, died at his home, April 19, from senile debility

Caleb M Emert, M D, Elizabethton, Tenn, College of Physicians and Surgeons, Baltimore, 1884, aged 75, a veteran of the Civil War, died at his home, April 25, from cerebral hemorrhage

Bertram Leslie Longenecker, M D, North Stonington, Conn, College of Physicians and Surgeons in the City of New York, 1890, aged 48, died at his home, April 29, from pneumonia

Franklin T Fenton, M D, Detroit, Pulte Medical College, Cincinnati, 1891, aged 51, formerly a member of the Michigan State Medical Society, died at his home, May 7, from pneumonia

Hugh Francis Quinn, M D, Bangor, Me, Medical School of Maine, Brunswick, 1909, aged 36, a member of the Maine Medical Association, died at his home in Bangor, about April 30

Samuel McGogney, M D, Castle Shannon, Pa, Jefferson Medical College, 1879, aged 59, died in the South Side Hospital, Pittsburgh, May 4, a few hours after a surgical operation

Robert Lee Tays, M D., Herkimer, Kan, Northwestern Medical College, St Joseph, Mo, 1893, aged 66, for several years coroner of Marshall County, died at his home, April 30

Garland Silvia Saylors, M D, Floral, Ark, University of Arkansas, Little Rock, 1914, aged 28, a member of the Arkansas Medical Society, died suddenly at his home, May 4

Henry H Miller, M D, Rossville, Kan, University of Pennsylvania, Philadelphia, 1872, aged 64, for forty-four years a practitioner of Kansas, died at his home, May 1

Joseph Oswalt, M D, Irving, Kan, Kansas City (Mo) Hospital College of Medicine, 1888 aged 78, a practitioner for more than forty years, died at his home, April 29

John M Mulholland, M D, Pittston, Pa, Eclectic Medical Institute, Cincinnati, 1875, aged 65, a member of the City Health Board of Pittston, died at his home, April 25

John M Lisle, M D, Columbus, Ohio, Starling Medical College, Columbus, 1875, aged 68, a veteran of the Civil War, died at his home, May 4, from heart disease

John Deal, M D, Riverton, Ill, Vanderbilt University, Nashville, Tenn, 1878, aged 67, a Fellow of the American Medical Association, died at his home, February 3

Charles Sinclair Stone, M D, Boston, Harvard Medical School, 1886, aged 56, a Fellow of the American Medical Association, died at his home, April 22

George W Metzgar, West York, Pa, (license, Pennsylvania, 1881), aged 61, a practitioner since 1877, died at his home, March 31, from pericarditis

John Aubrey Vaughan, M D, Brooklyn, Eclectic Medical College of the City of New York, 1891, aged 70, died at his home, January 29, from nephritis

John G Nugent, M D, Chipman, N B, Cincinnati College of Medicine and Surgery, 1876, aged 74, died at his home, January 10, from pneumonia

George Franklin Ritchey, M D, Mechanicsburg, Pa, Jefferson Medical College, 1889, aged 50, died at his home, April 23, from heart disease

Andrew Albert Johnston, M D, Unity Station, Pa, University of Pittsburgh, Pa, 1891, aged 61, died in the Columbia (Pa) Hospital, April 24

Cyrus W Shafto, Asbury Park, N J (license, New Jersey 1892), aged 44, died at his home, April 25, from cerebral hemorrhage

David Duncan, M D, Chicago, Hahnemann Medical College, 1887, aged 68, died at his home, May 3, from heart disease

Marriages

WALTER LOUIS MACHEMER, M D, Buffalo, to Miss Fanny Carter of Canisteo, N Y, at Bath, N Y, May 1

WILLIAM OSCAR BENJAMIN, M D, Detroit, to Miss Helen M Foote of Minneapolis, April 22

WILLIAM THOMAS DEAN, M D, to Miss Frances M Claiborne, both of St Louis, May 1

FLOYD H SPENCER, M D, to Miss Mary Dalgarn, both of St Joseph, Mo, April 29

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

THE WINE OF CARDUI SUIT

(Continued from page 1575)

April 20, 1916, Afternoon

TESTIMONY OF DR JOSEPH BOLIVAR DE LEE

The Court met pursuant to recess Dr Joseph Bolivar De Lee was called as a witness for the defendants

DIRECT EXAMINATION BY MR T J SCOFIELD

Dr De Lee testified that he graduated from the Northwestern University Medical School of Chicago in 1891, was intern in the Cook County Hospital for a year and a half For nearly one year, he was engaged in general practice and then did postgraduate work abroad in the universities of Vienna Berlin Paris and London He was attending obstetrician at the Cook County Hospital for several years and has been consulting obstetrician for ten or fifteen years He is also attending or consulting obstetrician in the Chicago Lying-in Hospital, Mercy Hospital, Provident Hospital and Evanston Hospital and Silver Cross Hospital in Joliet He practices obstetrics as a specialty and has held the chair of obstetrics in the Medical School of Northwestern University since 1897

Q—Doctor will you tell the jury approximately if you can remember the number of obstetrical cases which you have had charge of or have been under your direction? *A*—The word obstetrical cases is a little bit too broad, I will specify if you please

Q—Very well *A*—The number of actual confinements or deliveries that I have conducted myself with my own hands would be approximately thirty five hundred—three thousand five hundred—and in addition to that I have been called in as counsel or I have attended as instructor or as spectator in four or five thousand other cases, that occurred in the various hospitals with which I am connected, or that occurred in consultation as I say where I did not have the direct care of the patient but as you may say, sat in' on the case Four or five thousand

In addition to that the institutions with which I am connected of which I was the head would represent between twenty and twenty five thousand case and in these cases, I would have the responsibility in directing the course of practice of that institution, and in that way the pathological cases—the complications—would come to my notice, and thus I would get the experience from the pathological cases

Dr De Lee then described to the jury what is meant by pregnancy and labor, and mentioned some of the various complications which might occur He illustrated with a mannikin and with charts to the jury the normal female pelvis and the changes which the uterus and other organs undergo during pregnancy He showed the pelvis in a normal woman and the head of a baby and indicated the mechanism of normal labor He then showed to the jury the many complications which may occur due to various presentations, etc, stating that there are 136 different positions in which the baby can present He then showed to the jury a contracted pelvis and the impossibility of normal labor when such a contraction occurs

Dr De Lee said that he has had no experience with carduus benedictus

Q—Have you had any experience with the use of viburnum prunifolium? *A*—Yes

Q—What experience have you had with it? *A*—Years ago I gave large quantities of extractum viburnum prunifolium for the prevention of miscarriage.

Q—Well what was your experience with it Doctor? *A*—I found that it was useless and expensive and discontinued it.

There was then read to Dr De Lee a hypothetical question similar to that which has been read to other witnesses, and a statement from the Home Treatment Book under the heading, 'Disorders of Pregnancy" He stated that in his opinion the hypothetical medicine would not assist in making childbirth easier by reason of its gentle, building tonic, strengthening effect on the female organs and sexual parts concerned in the birth of the coming child"

His reason is that it is impossible for such a combination of drugs to correct a malpresentation and relax a rigid cervix It would not make child birth easier There was then read to Dr De Lee a second statement from the "Home Treatment for Women" under the same heading "Disorders of Pregnancy" In reply he stated that the hypothetical medicine would not have a good effect in giving health and life force to the woman

A—I would consider it would have a bad effect on the child It is generally believed that alcohol should not be given during pregnancy because of its effect on the child, that is given continuously because of its effect on the child And this question is just with reference to the child, is it not?

Q—Yes Well both mother and child Well particularly with reference to the added health strength and life force of the mother? *A*—The life force of the mother—no, I would say that alcohol would be not the best remedy to be given continuously during pregnancy for its effect upon the strength of the mother

He was then read a third statement from the "Home Treatment for Women" to the effect that "No one need be afraid of taking Wine of Cardui during pregnancy Its action is gentle and strengthening and it can never do anything but good"

Q—What is your opinion? *A*—That that statement is erroneous and misleading The medicine the hypothetical medicine which you have given me to consider has both actual and potential qualities for doing harm

Dr De Lee then defined for the jury puerperal eclampsia and the general understanding of this condition

ECLAMPSIA

Q—Now Doctor during pregnancy and when these kidney conditions to which you have referred or these cases which may lead to eclampsia are present how can you determine that fact in advance of labor? *A*—By careful watching of the patient for symptoms of the poison and also by taking her blood pressure regularly and by examining her urine for albumin

Q—Now when you discover a condition of abnormal blood pressure or blood pressure that is not satisfactory or albumin in the urine what do you do? *A*—We put the patient on a very strict diet put her in bed and unload her bowels and we try and get her emunctories that is her organs which throw off poisons very active and failing to get rid of the poisons in this way we occasionally interrupt the pregnancy, because it is the pregnancy which is developing these poisons and since we cannot remove the poisons we have to remove the pregnancy

Q—Now doctor, assuming that Wine of Cardui corresponds to the hypothetical solution which I have described to you, have you an opinion whether or not the use of Wine of Cardui would have any effect in correcting the kidney condition which you have just described if taken during pregnancy? *A*—Yes I have an opinion about that

Q—What is that opinion? *A*—That it would be not alone useless but harmful

Q—In what way would it be harmful? *A*—In two ways The kidneys during pregnancy are the most vulnerable portion of the woman s system Any bad condition that affects the woman during pregnancy is most likely to settle on her kidneys. Alcohol administered continuously during pregnancy has a bad effect on the kidneys. And the kidney is already overworked during pregnancy it is generally admitted that the kidney is overworking it is excreting for the baby and for the mother and an organ that is already overworking should not be given alcohol—that is should not be given additional work in excreting alcohol.

And while that is a real objection there is another objection which is none the less real, in fact, more active and that is the covering up of the symptoms and lulling the woman into a sense of security You give a remedy that may be useful and tell a woman 'now take this and you will be all right and she is likely to accept it as a fact and neglect to bring her water to the doctor for examination Oh I am going to be all right I am taking this medicine.' She won t go to have her blood pressure taken. And a contracted pelvis of that class (illustrating with pelvis) may pass unnoticed until labor comes on and the time is gone to do anything

Or a diabetes, for example might pass unnoticed A woman with diabetes during pregnancy If she were to take this hypothetical medicine, with the alcohol and the bitter stomachic it would increase her appetite perhaps and she would eat more food of an antidiabetic nature — that is not of a diabetic nature — I mean something that should not be taken in diabetes She will eat more food than she should Whereas if she had not taken this medicine she would not have had such an appetite That is the reason I say that it has both actual and potential bad effects

The witness then defined and illustrated with the aid of the mannikin extra-uterine pregnancy

Objection was made to the introduction of the witness' opinion as to the use of Wine of Cardui in extra-uterine pregnancy, the court stating that the witness had already stated that in his opinion it would not benefit a woman in any kind of a pregnancy

TREATMENT OF CONTRACTED PELVIS

Q—Doctor, in cases of contracted pelvis in connection with child birth, what do you do under such circumstances? A—It is very necessary to discover a contracted pelvis early in pregnancy We let the woman go on to term, except when there are other conditions which indicate the termination of pregnancy before term, which term means the end of pregnancy, nine months We let her go to term Then knowing that she has a contracted pelvis we do not always let her go into labor, but we either do a cesarean section, take the baby out through the belly, or else we so conduct the labor that the woman should not get into a precarious condition before it is too late to do anything to save her and the baby There are a great many methods Sometimes we leave the woman go to labor and see if she cannot deliver herself Then we do a pubiotomy, that is, we cut the bone here Or occasionally we apply instruments like forceps

Q—Now, during your experience have you ever performed that operation? A—I have performed 85 cesarean sections, and over a thousand forceps operations, and innumerable other operations for this purpose

Q—I suppose, doctor, you have written considerably on these different subjects, have you? A—Yes, yes

CROSS-EXAMINATION BY MR HOUGH

Dr De Lee testified that he recommends that a woman should apply to her physician as soon as she knows she is pregnant This should be done with a view toward nipping in the bud such complications as may affect her life or that of her baby

A—The second proposition, as to when the patient should enter the hospital, that is more or less domestic A woman that lives out of town—and thousands do come every year to Chicago—is requested to live in a hotel near the hospital and bring her urine every two weeks to the hospital, and have her blood pressure taken Then if she already has any serious trouble she is put in the hospital to await the confinement in the hospital A case that I am going to do cesarean section on I would like to have in the hospital for three weeks, to avoid the possibility of marital relations, to get the patient into good physical condition for the coming event

Q—In this connection, in your book you say you frequently treat the husband What do you mean by that? A—In what connection was it said?

Q—Don't you recall that statement in your book? A—Oh, yes, I have treated the husband in many different connections

Q—What did you mean when you said that? A—I will have to give you all the conditions If the husband has gonorrhea I would like to cure him up before the wife gets pregnant If the husband has syphilis I would like to cure him up before he impregnates his wife

Q—You mean treat the husband then before the wife becomes pregnant? A—Of course

Q—You don't refer to a treatment of the husband after the wife was pregnant? A—Well, you might stretch it to mean that As far as treating the husband is concerned for any condition affecting the woman's labor, I would say by the time the child was conceived that he had passed out of the range of treatment During pregnancy I could imagine certain conditions where I should recommend treatment of the husband

Q—I know what you mean by that statement You mean treat him before pregnancy? A—Yes, as a rule

Q—And not treat him after pregnancy? A—I could still imagine a condition where I would treat a husband after pregnancy

Q—I am not asking you what you could imagine I am asking you what you mean by the statement in your book You mean treating him before pregnancy? A—In that particular connection

Q—Yes A—It is pretty hard for me to answer a question that generalizes on all the subjects or conditions where I would treat a husband—to answer that in one answer If you will tell me just what you want I will answer it

Q—Now when you are not going to perform cesarean section how early do you want the woman in the hospital? A—The majority of women in Chicago wait until the labor pains begin, and then they come to the hospital

Q—How soon is that before delivery, as a rule? A—Varies all the way from—well, sometimes they are delivered in the taxicab or on the stairs of the hospital Again, they may be in the hospital two or three days in labor

Q—But that is not what you recommend? A—No, that is not what I recommend And what I recommend, and what nature does, are two different things

Q—I am asking you how early you want them to come to your hospital? A—The minute they know that they are in labor As soon as they think that the labor has begun, that moment They should not wait They should come to the hospital And if they have been mistaken, why all right, come there, and then they can go home the next night

Q—Well, would you like them there three days before? A—If I can have them there then, yes If I knew exactly when labor was going to occur I would say, "Yes, please be in the hospital three days before labor is due" That would be very nice

Q—The practice of obstetrics is on a very low plane, isn't it? A—The practice is still on too low a plane It ought to be higher, and it is going higher every day

Q—You mean by that every woman who is about to have a child should go into a hospital and have a doctor on hand all the time? A—That would be ideal

Dr De Lee described his method of examination and treatment of a patient who comes to a physician after the first month of pregnancy If drugs are given they are given for conditions that are pathologic Asked concerning disturbances of urination, he stated that the subject would have to be considered separately in each case and that discrimination must be made very careful Nobody but a doctor could tell just what medicine to give in any single case

Q—Do you mean all doctors could do that, or only a few? A—Not all doctors I wish they could

Q—You mean only a few doctors in your class? A—No, a lot of them besides me

Q—Do you mean a lot of them? A—Yes, I am happy to say, a lot of them

Asked to suggest drugs which would permit the flow of urine, he mentioned hot tea, saffron tea, camomile tea and infusion of digitalis He would avoid tinctures and extracts because of the irritant action of the alcohol In cases of constipation he would modify the diet, give liquid petrolatum for its lubricant effect and recommend stewed prunes, perhaps with addition of a little senna

Q—Did you ever give regulin? A—Regulin—I gave it some years ago I forget now what it is I think it is a sort of agar agar preparation Chinese preparation—agar agar—

Q—No A—Well, sulphate, phenolphthalein

Q—No A—Then I don't know what it is

Q—Do you mean to say you gave it and didn't know what it was? A—No, my brother asked me about it, and I confess I don't know what Regulin is I don't believe I gave it But as a rule I stay away from cathartics Then if I have to give a cathartic I have a very favorite combination It contains nux vomica, cascara rhamnus purshiana and rhubarb It works very nicely in combination It is a sort of a synergetic affair

Q—Did you say synergetic? You mean synergistic, don't you A—Well, you can say synergetic

Q—It is not a question of etymology A—I say synergetic If you want to say synergistic you may do so

Q—Do you mean to say that they mean the same thing? A—I will not haggle with you on a question of etymology

Q—The etymology is not involved I am simply asking you if you mean synergistic A—I won't argue that with you Have it synergistic or synergetic

Q—Go ahead A—They act synergistically or synergetically they act together, one helping the other

Q—Any other medicines that you give? A—I don't give it as a continuous cathartic

Q—Any other medicines you give for that condition? A—Do you mean of constipation?

Q—Yes A—I give milk and molasses enemas Enemas of milk and molasses and water

Q—That is all you can recollect? A—That is all I can recollect now

Q—What did you give before you knew anything about Russian oil? You haven't known about it always? A—No, that is a rather recent application I gave the tonic laxative which I have mentioned to you, and I gave agar agar, which I thought was regulin when I mentioned it, because it is given under a great many different trade names And Pluto water Epsom salts

Q—You are not opposed then to proprietary or secret remedies, are you? A—Well, if I know what is in it I don t oppose them on general principles If they do the work

Q—It doesn't make much difference what is in them, if they do the work? A—Oh, yes it makes a difference

Q—If it does the work? A—Oh, yes, it makes a difference

Q—If it does the work? A—I am careful

Q—Even if it does the work? A—Oh, yes, it makes a difference It does not always follow there, because sometimes they may do the work and they do harm at the same time

Q—You mean because of another ingredient? A—Because of another ingredient That is the objection to prescribing things that have several ingredients You get the effect of the one that you want but you have to take the effect of other things that you do not want Now if the disease that you are prescribing the remedy for is so bad that you are willing to take the effects of the other remedies in order to get the good effects of the one, that is the doctor's business to decide, and he can decide it as a rule

Q—Now are there any other conditions than constipation and bladder trouble which would require medical treatment, that is medicines given through the mouth, during pregnancy? A—Yes

Q—What other conditions? A—One of the most common conditions which I have met is frequent miscarriage Women have a history of frequent miscarriage for apparently no reason, and if I can find syphilis, as a cause of that, why, of course, I give antisyphilitic medicines If it is malaria—sometimes they have that

Q—You do not give that in the mouth? A—What?

Q—Antisyphilitic medicines? *A*—By mouth

Q—Do you? *A*—Why of course

Q—You do not believe in salvarsan? *A*—Yes, yes

Q—You do not give salvarsan by *mouth do you?* *A*—No, you give that intravenously

Q—I thought nobody gave anything but that nowadays *A*—I will not testify as an expert for the genito urinary specialist but if I had syphilis I believe from what I know of the remedies I would rather take the old fashioned treatment by mouth and the *inunctions instead* of salvarsan, but, as I say I do not testify to that as an expert

Q—What is the next then? *A*—If a woman has malaria, I try and treat the malaria as a cause of these frequent abortions If she has tuberculosis, I try and treat the condition that it presents in brief, in any pathological condition that requires the use of *medicines by* mouth I do not hesitate to give them providing the medicines do not interrupt the pregnancy—they don t have a bad effect on the pregnancy

Q—But you never give any *medicines* which *contain* any alcohol because the alcohol is dangerous during pregnancy? *A*—*That is* too broad Occasionally you have to give a medicine containing a small amount of alcohol

Q—What would you call a small amount of alcohol? *A*—Ten or fifteen drops

Q—Well, what per cent? *A*—Wouldn't the per cent depend upon the amount of the remedy? Ten or fifteen drops of alcohol two or three times a day a couple of weeks or a month will not hurt the patient in my opinion More might But as I say, I avoid those remedies.

Q—What is that? *A*—I avoid, as a matter of practice, the use of alcohol in pregnant women

Dr De Lee was then cross-examined as to the percentage of alcohol in the infusion of digitalis He said that he prepares an infusion by pouring some boiling water over an ounce of leaves

Q—You said the infusion of digitalis does not contain alcohol you are mistaken about that aren t you? *A*—Very well I would be glad to admit I was mistaken I know I made the infusion the last infusion last time I used it.

Q—Well but the Pharmacopeia prescribes how it should be made, doesn t it? *A*—Very good

Q—And it requires 100 c.c of alcohol doesn t it? *A*—I do not know I never read the Pharmacopeia.

Q—You mean you practice without reference to the pharmacopeia? *A*—Yes.

Q—Or the National Formulary? *A*—Yes

Q—Or any *medical book that anybody ever wrote?* *A*—*Oh that* is different

Q—What medical books do you rely on or do you have confidence?

After objection which was overruled, the witness answered

Mr Hough *Q*—What do you mean by that that is different ? *A*—I mean this that when I read a medical book I take the man who is writing it and see what I consider his value as an authority is and if he says something that I don t agree with I don t accept it in practice. He may say a whole lot of things in that book which I know from my own experience are fallacious so when you say don t I practice according to medical books I say right off that is different

Q—What use do you make of medical books? *A*—To add to my general knowledge

Q—You mean merely to find out who agrees with you and who disagrees? *A*—No, no that is different. I want to know what people are doing And when I find something in a medical book that appeals to me as *being reasonable I will use it in my* practice. *If I find it* unreasonable I discard it

The witness was asked which medical books contain anything which he regards as reasonable Objection was made to the question and sustained He was then asked whether he did not start with some list of books when he first began to study to which he answered that he did Objection was made to the question but was overruled

Mr Hough *Q*—Then you followed in your original practice what the medical books said? *A*—Yes every doctor does that.

Q—Then you formed your opinion later from your own experience? *A*—Exactly

Q—Which might have the effect of modifying what some medical books said? *A*—As a rule.

Q—But *has your experience taught you to disbelieve the majority* of things that are in medical books? *A*—I would hardly know how to answer that. That is too sweeping a generalization

DEATHS IN LABOR

Q—Well I will not insist upon your answering it When you say in your book *that 20 000 women die in the United States every year* from direct or indirect effects of labor ' what do you mean? *A*—These statistics furnished us by the United States Census Bureau of last year—that is the la t time they came out—enumerated the deaths of 10 010 I think that is about it—it is around ten thousand deaths of women in childbirth Those are reported deaths We know they died because the death certificates came in That represents the returns from the registration area of the United States, of 60 odd per cent —I am not sure of the exact figures if I had known I was going to be asked this question I would have brought *them down*

Now, then if 60 per cent area of the United States is registered and the women dying in *that area are reported to the Washington* Census Bureau the other 40 per cent of deaths not being reported it would be pretty safe in saying that if ten thousand women die in the registration area another four thousand every year will die in the nonregistration area, which would give us 14,000 women that die in the nonregistration area—that *is, I mean* in the total United States That is general, and I will not insist on the accuracy of all those things but it is general Now every year, gentlemen, a certain number of women die during childbirth and after, where their deaths are not reported to the authorities, because they die under conditions that might be suspicious *child bed fever for example,* or somebody made a mistake and they are reported as dying from typho malarial fever or some other condition A certain proportion of those are so reported

Then again a woman will have a contracted pelvis, and some doctor will use forceps where *he should have done cesarean section* and tore that poor woman all to pieces She has to go back again in a year or so and be repaired those stitches put in, and the uterus that has been misplaced put in order by an operation, and she dies as a result of that operation Now that operation while it was the immediate cause of death dates back and should be quoted in this six thousand And my judgment is that another six thousand would be a very small estimate to put upon those women that die from the immediate and remote effects of childbirth

Q—Were they all cases where the doctors were in charge? *A*—*No doctors and midwives*

Q—Doctors and midwives? *A*—Yes

Q—Those are the reportable cases? *A*—Well they were reported cases as they came within the knowledge of the Health Department

Q—What did you mean about the number of women who died in *childbirth but who were operated on under another diagnosis?* *A*—I just told you that that they—

Q—You mean when it was a mistake in diagnosis? *A*—Yes, through a mistake—yes, a mistake in diagnosing

Q—You don't include the abortions in that, do you? *A*—I would *have to look at the statistics to see if abortions were included in that* The American statistics are not very useful to draw positive conclusions from

The witness was then asked concerning the various types of anemia and he said that he usually gives an alterative tonic, for example, a mixture of iron, arsenic, mercury and iodin He was asked concerning the preparation of digitalis and he stated he has prescribed an infusion made up according to the pharmacopeial preparation

There was read to the witness a prescription for atonic constipation attended with flatulence which he is said to have prescribed consisting of fluidextract of cascara sagrada, 30 c c , tinctura rhei aromatica, 30 c c , tinctura nucis vomicae, 20 c c , elixir taraxaci comp , N F , enough to make 120 c c

The witness was asked how much alcohol is contained in these preparations He answered that the patient gets 30 drops of the medicine three times a day He was questioned specifically concerning the percentage of alcohol in each ingredient He finally stated that the total amount of alcohol represented in a dose would be not more than 15 drops The patient is instructed not to take that continuously She is given only enough to last ten days and is instructed to discontinue it as soon as possible

Council for the plaintiffs argued that there were 24½ drops, finally agreeing that he made a mistake, the witness stating

The Witness—I granted you fifteen drops, and, as a matter of fact it is 7½ drops of pure alcohol.

Mr Hough *Q*—Now are there any other prescriptions? Does that remind you of any other prescriptions containing alcohol? *A*—I prescribe very little drugs. I am rather opposed to indiscriminate drugging and I am therefore very discriminating in using them I use alcohol in a nipple wash compound, spirits of lavender

Q—I don t mean outside I am talking about in the mouth. *A*—Yes yes Oh yes I use ergot fluidextract of ergot for postpartum hemorrhage Is that what you wanted me to answer?

Q—Yes that is one *A*—And I also use ergot for the abortion—

Q—How much ergot? *A*—The patient gets ten to fifteen drops three times a day

Q—Of *alcohol?* *A*—No, fluidextract of ergot. If she took more than that she would get ergot poisoning

Q—How much alcohol does that contain? *A*—I think ergot contains about 50 per cent of alcohol and so she gets 5 to 7 drops of alcohol

Q—Doctor it has *been testified to here* that pregnancy is a normal function What is your opinion about that? *A*—You have opened up a very interesting subject.

Mr Hough—I thought I would

Mr Walker—And you did not have to go to the figure.

Mr Hough *Q*—Your *opinion* is that it is pathological is it not? *A*—With certain modifications pregnancy is a natural function

Q—Pregnancy and puberty are both natural in a state of nature? *A*—Yes

Q—But in our state of civilization they are both really physiological—

Mr Walker—Pathological

Mr Hough—Pathological, I should say

The Witness—They are very often pathological, *so often that* they require medical attention from start to finish, if it is possible to give the patient the medical attention

Q—Now you have been testifying, Doctor, with reference to ideal conditions, haven't you? *A*—We always strive for ideals

Q—What do you suppose the poor woman who lives back in the country is going to do if she cannot come to your sanitarium? *A*—Well, most of the women don't come to my sanitarium or any sanitarium—

Q—I mean any sanitarium *A*—At least I have no sanitarium And what a woman in the country should do would be, as soon as pregnancy has declared itself, to go to the nearest reputable physician and let him give her whatever care it is possible under the circumstances then and there existing, warn her against the complications which are likely to arise, insist that her husband when he comes to town, as he probably does frequently, bring to him a bottle of her water and at least examine the urine These few things any woman can get, *no matter* where she is, and pretty nearly every doctor, cross roads doctor, knows enough to manage those cases

The witness then testified again as to the number of deaths occurring from childbirth, and as to the symptoms of extra-uterine pregnancy

The average physician can tell on examination whether or not the woman is going to have a difficult time in labor He stated that the head of the fetus might be compressed to a thickness of three sheets of paper

Q—Doctor, when you said that this hypothetical medicine, taken during pregnancy, would have no effect whatever, except the effect of the alcohol, did you mean in any condition attending pregnancy? *A*—Let us separate that into two parts

Q—First, did you make that statement? *A*—Not exactly

Q—How did you state that? *A*—I do not remember exactly how I stated it I can answer the question, however to your satisfaction, if you will let me separate it into two parts

If a woman needed a little appetizer, and I gave her some bitter medicine, whether it is viburnum or anything else it might stimulate her appetite a little If the woman needed alcohol in the medicine and I gave her alcohol—I would give her alcohol *if she needed it by the prescription*, and then it would have the effect of the alcohol

Q—Well, suppose the medicine was hepatic? *A*—An hepatic stimulant, is that what you mean?

Q—Yes *A*—How much would I have to give her in order to get the hepatic stimulant?

Q—No, suppose it was hepatic in the doses in which it is given, an hepatic stimulant in the doses in which it is given *A*—In order to give that dose, I would have to give of that particular hypothetical medicine, so much that the alcohol in it would be prohibitive

Q—Well, you lose sight of the hypothesis you are supposed to assume You know nothing about carduus benedictus *A*—Practically

Q—You have never used it? *A*—Practically none

Q—Well, have you ever used it? *A*—Yes, I prescribed carduus benedictus once

Q—When was that? *A*—About two weeks ago Interested in what was going on, I had a case which I thought might be useful

Q—Where did you get the carduus benedictus? *A*—What?

Q—Where did you get the carduus benedictus? *A*—If you will allow me, I will tell you So I prescribed it, and before the patient—it was a case of hemorrhage, threatened abortion and I told the woman to go home and go to bed, and rest in bed, and I gave her this prescription, and her husband went to fourteen different drug stores and could not get it In the meantime the patient got well So that when I say that I have practically no experience, that is what I mean

Q—Then you have no experience *at all*? *A*—Well, that is for you to decide You asked me, and I am telling you

Mr Walker—Why sure, she was cured by the mere prescription He has got the experience All you had to do was to suggest it, and the woman got well

The Witness—Well, the woman did not know it

The Court—Why, he only told her husband

The Witness—Her husband did not know what was in it

Mr Walker—She got cured by telepathy

Mr Hough *Q*—Do you mean the woman herself, did not come to you? *A*—What do you mean?

Q—This patient, she herself, did not come to you? *A*—Oh, yes, sure

Q—You gave the prescription to her, didn't you? *A*—No

Q—You mean her husband came with her? *A*—Now, wait a minute I want to recall the incident I don't remember whether her husband was there or not, but anyway she was an ignorant Russian, Jewish woman, and I doubt if she could read and I doubt if her husband ever looked at the prescription, and I am telling you I gave her the prescription, and she went home and went to bed, and did not get the medicine until late the next night They had to send to the wholesale druggist, I guess, to get it, and by that time the hemorrhage had stopped

Q—Did you call on her the next day? *A*—No, the husband telephoned me at the end of the week I told him to call me up and let me know the effect of that medicine, and he told me what I told you So I said, "Wait another week and bring your wife down" He went away and so I examined her and she was all right That is all the experience I have had

Q—You did not see the medicine that she got, did *you*? *A*—No Well, that she did not get

The witness was asked concerning the dosage which he prescribed He stated that he could not give sufficient of the hypothetical medicine mentioned to get the effect of either of the principles mentioned without giving *more* alcohol than he would wish to prescribe

He was asked whether he assumed that volatile oil in the *hypothetical* medicine had no effect He stated that volatile oils in the combination were so small in quantity as to be negligible He stated that volatile oils as usually given are inert He was asked what volatile oils that he could remember that had any effect He stated that even supposing that the diuretic and diaphoretic principles are present in sufficient amount to give that action he still considered this mixture would not be safe to give in pregnancy not *only* because of the amount of alcohol but also because diuretic or diaphoretic drugs *must not* be given without the physician knowing what he is giving them for

The further hearing of the case was adjourned until April 21, 1916, 10 30 a m

April 21, 1916, Morning

TESTIMONY OF DR JOSEPH B DE LEE (*continued*)

The Court met pursuant to adjournment Dr Joseph B De Lee resumed the stand for the defendants

CROSS-EXAMINATION BY MR HOUGH

Dr De Lee was asked *as to his* knowledge of alcohol He stated that it was general He was asked

Q—Are you familiar with the statement of Dr J Clarence Webster on the subject in his book on Diseases of Women"? *A*—I don't know what he says about it

Q—Well is this statement a fact "Brandy or whiskey is valuable where there is much exhaustion As much as 10 or 12 ounces, or *even more, may be administered in 24 hours chiefly for the food value*, though the stimulant action is also important" Is that a fact?

Mr T J Scofield—I object to that question, if the Court please

The Court—What is the objection?

Mr T J Scofield—I don't see how it is cross-examination in any way, or how it is material

The Court—Well, this is not what Dr Webster said, I mean so far as the question is concerned The witness said he did not know what Dr Webster said in his book Now, Mr Hough has a right to ask him whether alcohol in these doses, under these conditions he regards as proper

Mr Hough *Q*—Is that a true *statement, in your* opinion?

The Court—Do you agree with that statement?

The Witness—*Since that is an important* statement, and I want to know the details, might I ask you to read it again?

Mr Hough *Q*—Well, the statement that is important, is the fact that it may be administered in as large quantities as 10 or 12 ounces in each 24 hours for its food value as well as for its stimulating value *A*—Under what subject, may I ask, is that recommendation given?

Q—Now, would a woman during pregnancy be able to oxidize or assimilate freely less alcohol than she would in any other menstrual disturbance? *A*—You have assumed that pregnancy is a *menstrual* disturbance That is an erroneous assumption

Q—Well leave out the word 'other" Any *menstrual* disturbance? *A*—Offhand I would say that the *woman's* power of assimilating and getting rid of toxic (*poisonous*) matter—toxic means poisonous—I would say that a woman's power of assimilating and getting rid of toxic products during pregnancy would be diminished on account of the weakness of the kidneys, the vulnerability of the kidneys to toxic influence

Mr Hough—I ask that that answer be stricken out as not responsive

The Court—It is not directly responsive

Mr Hough—And it has no bearing on what I asked, which was whether a woman in pregnancy would assimilate more or *less* alcohol than in menstrual disturbances without pregnancy? *A*—Assimilation—I would like to explain to the jury—consists *in the* using up of a medicine and its removal from the body *That is part of the* function of assimilation And I have *not made* any pharmacological experiments to determine how *much* alcohol a woman can assimilate and get rid of during pregnancy as compared with the same woman during the menstrual *periods* I doubt if such pharmacological experiments have been *made* So that I can only generalize in that way and use *my* general information regarding poisons, and we do know that all forms of poison are less easily gotten rid of during pregnancy That is generally understood

Objection was made to the witness stating whether the statement of Dr Webster was true or untrue

Mr Hough Q—Will you state then, whether in your opinion a woman suffering from any female disease can assimilate so much as ten or twelve ounces of brandy or whisky a day? *A*—That is not a statement for an expert on obstetrics to decide That is a pharmacological—

Q—Have you no opinion on the subject? *A*—What?

Q—Have you no opinion on the subject? *A*—The general impression is that a woman can assimilate two ounces of alcohol two or three ounces of alcohol in a day Whether or not it is advisable to give that amount of alcohol depends on the case. The olden time treatment for childbed fevers was alcohol They would give as much as a quart of whisky a day, and it was said that women could absorb and assimilate as a food a quart of alcohol in a day — or whisky not alcohol Now my opinion is that that amount of alcohol—and I base my opinion on my own experience as I have tried it—that that amount of alcohol is harmful and not good

Q—What is the maximum amount, in your opinion which is not harmful? *A*—Well I have given in the form of an eggnog to stimulate the appetite, or to produce a little change in the diet or to encourage the condition I have given as high as an ounce possibly two ounces in a day But if the woman has a tendency to—

Q—Before you go on will you just explain how many drops there are in an ounce or two ounces? *A*—Oh I should say in an eggnog a woman gets a teaspoonful of whisky, sometimes two teaspoonsful of whiskey to brace her up over a depressed period

The witness was then asked if he relied on any statements made by THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION in forming his opinion He answered that he relied on all the literature he has read, things that he has heard in court and from various people He would not assume anything regarding a statement, he would wish to know who made it and would study each individual experiment and see whether the experiment suited him

Dr De Lee was asked if he would give the name of the woman for whom he prescribed carduus benedictus He stated that he preferred not to do so and would not care to give it privately to the counsel for the plaintiff The Court stated that where the case was brought out on cross-examination he doubted much if the Court should be required to direct the witness to furnish the name In the case in question Dr De Lee examined the patient in his office, for which the patient paid $2 He was questioned specifically regarding the details of the examination

Q—When she came back did she tell you what she had paid for the prescription? *A*—No I didn t ask her

Q—But you didn t expect it to do any good when you gave it to her? *A*—That is one of the reasons I prefer not to give you her name

Q—Why? *A*—I rather hesitate to let her know that I gave her a medicine that I did not think was going to do her any good

Q—Well, but you charged her for it too, didn t you? *A*—No, I beg your pardon

Q—Didn't you charge her $2? *A*—I charged her $2 I gave her a thorough examination I advised her to go to bed—a remedy which I believed was going to cure her

Q—Aren't you going to give her back the price of the prescription?

Mr T J Scofield—Oh, I object to that if the Court please

The Witness *A*—Did I give her back the price of it?

M Hough Q—You will won t you? *A*—If she should ask me I would gladly give her back But I gave her more than $2 worth of service I assure you I didn t charge her for the telephone calls Let us call that square on the prescription

Q—You mean you didn t charge her for the prescription then you charged her for talking to her? *A*—Oh yes, I get a lot of money for that

Q—When the husband telephoned to you what language did he use? *A*—I really don t know It may have been English or German I understand both equally well

Q—Did I ask you if you were continuing to attend her? *A*—Yes she is on my book I haven t heard from her She may have had her abortion and called in a local doctor That often happens Or she may be well and may have her abortion later and I may be called That class of patients are very uncertain They leave one doctor very often for another

Dr De Lee was asked to define eclampsia and state its causes He stated that the cause is said to be a poison or toxin The exact chemical nature of the poison is not understood

Q—Now under the head of eclampsia on page 362 of your book is this statement

> Eclampsia and allied conditions It is impossible to classify these diseases because the causes are unknown"

That is a correct statement is it? *A*—Oh yes in a general way I think it is impossible to classify disease

Q—At least it was a correct statement when you wrote the book? *A*—Yes it must have been or I probably would not have put it in

Q—Now since hearing Dr Kay testify on the stand yesterday you know what the causes are, don't you?

Mr T J Scofield—I object to that, if the Court please

THE COURT—Objection sustained

Mr T J Scofield—He is testifying from his own experience

Mr Hough Q—You heard Dr Kay testify? *A*—I heard Dr Kay Very good testimony

Q—You heard the testimony? *A*—Yes pretty good testimony

Q—You heard him testify as to the causes of eclampsia didn't you? *A*—He said something about constipation causing eclampsia. I thought I mentioned that too as one of the causes

The witness was then asked whether extractives from viburnum prunifolium could be of any benefit in eclampsia He stated that they could be of the slightest imaginable benefit He stated that he did not believe that 48 drops of alcohol three times a day would produce eclampsia, but he recited a case in which larger doses of alcohol did produce eclampsia He stated that there is authority for believing that alcohol should not be taken during pregnancy He was asked whether or not there is more eclampsia in Europe He stated he did not know that there was He stated that there was perhaps one case of eclampsia in 600 cases, but that statistics vary In Baltimore, for example, there is more eclampsia

The witness was then asked as to his knowledge of the treatment prescribed in the Home Treatment Book. He stated that he knew in a general way that the knee-chest position is recommended and keeping the bowels open He is not so expert on the Home Treatment Book as he is on his own book He understood from the Home Treatment Book that without taking Wine of Cardui a treatment could not do very much good

The witness was then asked as to his treatment of threatened abortion He defined habit-forming drugs and as the greatest habit-forming drug he mentioned alcohol He was then read extracts from the Home Treatment Book prescribing the diet suitable for the first months of pregnancy and stated that it is a very liberal dietary, but certain pregnant women ought not to be put on that diet

THE MIDWIFE

Q—Doctor, is a midwife an obstetrician? *A*—Is a midwife an obstetrician? In the olden times before we had obstetricians the midwives did the work and they got various names and the first was "The midwife which means a wife that stands midway between the husband and the real wife She was a mid wife In the olden times the husbands took care of the babies They were delivered sitting on the husband's lap Then came the midwife and they sat on her lap and in the 16th and 17th century the French midwives were called *sage femme* meaning wise woman They were also called *accoucheuse* which means to put a woman in bed

When the men in the beginning of the 16th or 17th century began to dabble in this particular branch (they had before but not to any particular extent) they chose the name accoucheur which means a man that puts a woman to bed In England they were called 'men midwives, but the men did not like that so they decided they ought to be called something else and they selected the word obstetrician which comes from the Latin word obstetrix to protect or assist and the Latin word 'status,' to stand as a protection. And I might say that that meaning of the word obstetrician is not sufficiently understood and practiced The obstetrician s business is to protect the patient from dangers threatening her and the baby

A great many men think that it is their business to help some woman out of trouble and of course it is to the extent of protecting them from trouble, but they give medicines and things which are not necessary So you see the origin of the word obstetrician '

Now, whether a midwife should be entitled to the term 'obstetrician would depend on how you take my description Her antiquity would certainly entitle her to a great deal of honor but her actual capacity nowadays would not entitle her to any high degree of honor

Q—You mean unless they have had some education along the lines of that subject? *A*—Oh no The usual obstetrician or the usual midwife of today, is a very ignorant, unconscientious and really impossible person the usual one

Q—They graduate then don t they? *A*—They do in Europe, and they have some schools for midwives but the class of women who undertake the study is not of a high grade and they forget very rapidly

Q—They graduate then in America? *A*—There is only one midwife s school in America of any standing whatever and that is the Bellevue Hospital in New York.

He was then asked some general questions as to the status of obstetrics in this country today

TESTIMONY OF DR. G FRANK LYDSTON

Dr G Frank Lydston was called as witness for the defendants

DIRECT EXAMINATION BY MR T J SCOFIELD

Dr G Frank Lydston has been practicing medicine for 37 years He is a graduate of Bellevue Hospital, New York He served at the State Hospital in New York, on Blackwell's Island, in the penitentiary hospital, and had for six months charge of the maternity service at Blackwell's Island He also served for a time as resident surgeon at the State Immigration Hospital, Ward's Island, New York For 30 years he was connected with the College of Physicians and Surgeons, of Chicago, as a professor in the Department of Diseases of the Genito-Urinary Organs He has seen perhaps from thirty thousand to fifty thousand cases in his practice and has written various articles on his subject

Dr Lydston defined inflammation and their causes and named some of the various bacteria which produce inflammations He mentioned some of the most common organisms which he finds in his practice gonococcus, colon bacillus and the spirochete He was asked to describe gonorrhea in the female The counsel for the plaintiffs admitted there would be no dispute on this question so that the answer was passed He was then asked to describe the syphilitic infection in the female, which was described extensively He described syphilis of the neck of the womb and defined leukorrhea as a symptom of a disease He has not had any experience with cnicus benedictus or viburnum prunifolium

The witness was then asked a hypothetical question similar to those asked of other witness and whether a hypothetical medicine such as had been described would cure inflammations of the female genital organs He stated that it was his opinion that it would not

Q —Why not, Doctor? *A* —Simply because, as you have read the hypothetical question involving this particular drug or preparation, you have shown nothing that would have any effect upon the cause of gonorrhea

Q —The cause of gonorrhea being what, Doctor? *A* —The cause of gonorrhea being a micro organism that would not be reached by this remedy taken internally, even though the remedy had any germicidal properties, which, in my opinion, it has not

Q —Now, Doctor, in reference to gonorrhea in women, I will ask you this question, whether this hypothetical medicinal solution which I will ask you to assume corresponds to Wine of Cardui, will act upon the cause of the disease and is, therefore, not a mere palliative, but a scientific and specific remedy, with a curative effect upon the seat of the trouble?

Mr Hough —What are you reading from, Judge?

Mr T J Scofield —From the Cardui Home Treatment, page, I think, 6

Q —Have you an opinion, Doctor, on that subject? *A* —I have

Q —What is that opinion? *A* —That it will not

Q —Doctor, what would be the effect, if any, of the alcohol content of such a medicine upon the gonorrheal condition—upon the condition of gonorrhea? *A* —That would depend largely upon what complications existed, and it would depend also upon the amount that was given You have stated how much there was in the single dose, but you have said nothing about how frequently it is given

Q —Yes The doses being repeated from three to four times every day *A* —In my opinion, the alcohol content would be injurious

Q —In what way, Doctor, and in what complications? That is a double question, perhaps *A* —Well, take for example the infective inflammation resulting from gonorrhea of the uterus It would tend to increase congestion tend to increase nervous excitability and sensibility, and in that way would lessen the resistance of the tissues to the inroads of the germ Anything which tends to produce congestion in the presence of infectious micro organisms almost invariably tends to increase the virulency of the infection, make it worse

The witness was then asked particularly concerning the effects of the hypothetical medicine on syphilitic infection Objection was made to the question, and, after argument, he was asked whether the hypothetical medicine would have effect on any inflammation of the womb He stated that in his opinion it would not have a beneficial effect

Q —Would it make any difference in answering your question—in your answer Doctor, whether the inflammation was produced from syphilitic causes or other causes? *A* —It would make a difference in this respect, that the use of that particular remedy, this hypothetical solution, would be even more illogical in the case of a syphilitic inflammation or ulcer of the neck of the womb, than it would be in other conditions—conditions from other causes—and it would be more likely to be injurious

There was then read to the witness a section from the Ladies' Birthday Almanac for 1913, concerning pain in the small of the back and the witness was asked to state two or three conditions which come in the line of his special work which might cause such a pain

PAIN IN THE BACK

A —Pain in the back is not a disease, but a symptom of a multiplicity of diseases It may not be a symptom of any one or more of a multiplicity of diseases, not only two or three, but a large number, and especially in the female, for example, all sorts of displacements of the uterus, anything that increases the weight of the uterus and brings tension to bear upon the ligaments or supports of the uterus is very likely to produce pain in the back That is a very frequent symptom And it may produce pain in the back not only by its direct dragging, but by its reflex effect upon the nerves supplying the back, and the reflex effect upon the nervous system in general

Abscesses in the pelvis, abscesses in the fallopian tubes, chronic inflammatory conditions of the pelvis, tumors of the pelvis, cancer of the ovaries, cancer of the uterus, cancer of the tubes, cancer of the cervix, cancer of the vagina, cancer or hemorrhoids or any other morbid condition of the rectum

Cancer of the bladder may produce it, stone in the bladder may produce it, inflammation of the bladder may produce it, gonorrheal infection may produce it in two ways, by increasing the weight and producing irritation of the uterus in one way, and it may produce it in the other way by infection through the blood, producing it in that way, affecting the muscles of the back, the sheaths of the muscles of the back, the tendons of the muscles of the back and ligaments of the spine

It may result from stone in the bladder, or stone in the ureter, particularly a stone in the ureter, a stone in the pelvis of the kidney It may result from sarcoma or a cancer of the kidney or a stone in the kidney It may result, and very frequently does in women, from a displacement of the kidney

That is about all I can think of offhand There are some more, I suppose

Q —Doctor, can you tell now—

Mr Walker —What is the matter with lumbago? Isn't that one?

Mr T J Scofield —Can you tell from the description of the pain—

The Witness —I should speak of rheumatism of the back Lumbago is not definite

Mr T J Scofield *Q* —Can you tell from the description of the pain, as described in the Birthday Almanac what the cause of that pain is—from the description given there—could you diagnose the condition, and tell the cause of the trouble, without examination?

Mr Hough —Objected to as incompetent, irrelevant and immaterial

The Court —He may answer

To which ruling of the Court the plaintiffs, etc, excepted

The Witness —No sir, I could not I don't think that any scientific physician would undertake to make a diagnosis of any condition merely from the symptom of pain in the back

Mr T J Scofield *Q* —Doctor what in your opinion would be the effect of the hypothetical and medicinal solution which I have described to you, assuming that it corresponds to Wine of Cardui, in the treatment of this pain in the back? *A* —Well, I think from the position of it, if it were given freely, that there might be some temporary alleviation of the pain, by virtue of the effect of the alcohol

Q —Where it is given, of course, in the doses I have already referred to *A* —I should think that might be so, yes I should think, however, the secondary effect of the alcohol—in fact, I am confident it would be in the majority of these cases, if not all the instances I stated, be injurious, particularly so where there is any inflammation of the urinary way, where a very small quantity of alcohol may result in extreme irritation

Mr T J Scofield *Q* —Now, Doctor, would it have any effect on the underlying cause of the pain, whatever that underlying cause might be? *A* —In my opinion it would not

The case was then adjourned until 2 o'clock the same day

April 21, 1916, Afternoon

The Court met pursuant to adjournment After discussion the Court adjourned until Tuesday Morning, April 25, 10 a m

April 25, 1916, Morning

TESTIMONY OF DR G FRANK LYDSTON (*continued*)

Dr G Frank Lydston resumed the stand in behalf of the defendants

CROSS-EXAMINATION BY MR HOUGH

Dr Lydston was asked as to the best treatment for gonorrheal infection He outlined what he would do in the case of a woman patient afflicted with gonorrhea He outlined the diagnosis, describing the use of the microscope and mentioned the use of the complement fixation test If the case was in its incipiency he would hope to cut the disease short by germicidal drugs, for example, permanganate of potassium varying in strength from one to five thousand to one in one thousand Douches should be given in the recumbent position with large quantities of hot water He would advise the patient concerning the danger of infecting others, particularly with relation to danger from gonorrheal conjunctivitis He would say to the patient "You must avoid absolutely stimulants of all kinds, even tea and coffee You must avoid all sorts of excitement particularly of a sexual character The best thing that you could do, would be to rest quietly in bed" If the disease had reached a moderate start, he would advise the patient to rest in bed in order to avoid a number of very serious complications which he mentioned If the patient were depleted he would prescribe tonics containing iron, arsenic, etc., and perhaps bitter infusions of quassia, columbo or gentian If the patient suffered from sleeplessness he would prescribe such sedatives as bromids and gelsemium, or small doses of chloral and veronal He would prescribe prolonged sitz baths He would attend to the condition of the bowels, it there was fever he would attend to that by appropriate remedies. The treatment would be directed chiefly toward destruction of the gonococcus

The witness would consider also the question of infection of Bartholin's glands, which he described He also described endometritis and its treatment, and spoke of extension of the inflammation to the fallopian tubes, with the formation of pyosalpinx

He then considered secondary peritonitis and appendicitis and discussed a case of this character in which he had recently performed an operation

He was then asked whether gonorrhea ever produced vaginitis He replied that vaginitis in gonorrhea is not an important element, more important are secondary infections of the glands, etc. He was asked whether he ever treated gonorrheal infection by simply keeping the parts clean He had not done so but practically always prescribed an antiseptic douche unless there were distinct contraindications

Q—Now, you stated the micro-organisms to be the cause of these infections Is it not also the nonresistance of the tissues does not that have something to do with it? *A*—That is obvious if the tissues were resistant to the micro-organisms we would never have any disease at all.

Q—And it is possible— *A*—And you would not eat unless you were hungry either

Q—Is it not possible to so strengthen the resistance of the tissues as that they can oppose the micro-organism? *A*—You are speaking of strengthening the tissues in general? We can so increase—we cannot increase the resistance of the tissues we have no method of increasing the resistance of the tissues so that we could be certain that we could prevent the inroads or action of any micro-organism pathogenic micro organism disease producing micro organism but we can relatively increase the resistance in reference to many of them

For instance tuberculosis A lack of resistance to the tubercular—the bacillus tuberculosis or the germ of tuberculosis or consumption, is the primary condition That, however is an entirely different thing. There is nothing particularly virulent about the tubercular micro organism as compared with this

Q—Would that be true in cases of gonorrhea? *A*—I am going to give that In the case of gonorrhea I don t care how you may increase the resistance I don t care how you may lower the resistance Whenever a virulent gonococcus attacks your mucous membrane—good night You are going to have gonorrhea, and that is all there is to it

Dr Lydston stated that everyone who is exposed to gonorrhea does not become infected because of resistance of the tissues and variations in susceptibility

Dr Lydston described leukocytes and their relation to combating infection Hyperemia in the beginning of infection would tend to aid the conditions, but is rapidly superseded by congestion which is not beneficial

Dr Lydston stated that he sometimes prescribes tincture of gelsemium, but that he does not know the exact alcohol content of it. He gives quassia in the form of infusion He gives digitalis in the form of infusion He stated that it is not necessary that the infusion contain alcohol

Q—When you prescribe medicine Doctor don't you pay any attention to whether there is alcohol in it or not? *A*—I might or I might not That depends entirely on the condition for which I prescribe the medicine the complications and the amount of alcohol in the preparation the frequency of the dose and the duration of the treatment I will state incidentally however that I avoid alcoholic preparations wherever I can

Q—Here is a preparation that you prescribe or that you recommend containing fluidextract of ergot tincture of gelsemium potassium bromid hyoscyamus aurantii do you know how much alcohol there is in that preparation? Now once again what is it? I will just let you read it (Handing book to witness) *A*—Thank you very much I was about to ask for that book I have not seen it for a long time

Q—You will find the prescription referred to on page 141 of your book *A*—(Examining book) Well you have helped me out here you have gotten it all written out

Q—I did not intend to give you any help but you can take advantage of it if you like. *A*—Oh I don t care to take advantage of it Something like 25 minims it would figure up

Dr Lydston did not consider that the alcohol in this prescription had any deleterious effect, as the bromid present was an antidote

Q—Would that amount of alcohol be cumulative, so that its effect would run over to the next dose? *A*—You mean cumulative in that it would stay in the system?

Q—Yes *A*—I have my serious doubts of it, but the effect of it would be cumulative

Q—That is, the beneficial effect would be cumulative? *A*—Let us speak of the deleterious effect, please

Q—Well would the deleterious effect be cumulative? *A*—It would

Q—So that the time you gave the second dose of it it is worse than the time you gave the first? *A*—Please stick to your question and don t try to trap me because I am not here for that purpose, Mr Hough

Q—I don t want to trap you *A*—You are trying to, and there is no use in it because you and I are reasonable men I am not going to lay any traps for you

Q—I am not trying to lay any trap for you *A*—The deleterious effect of the alcohol given as alcohol in 25 minim doses, either in one dose or however many times a day, if you will put your question in that way, then I will answer it

Q—Why not answer me whether the time you gave it, the second dose it would be worse in its effects than when you gave the first dose? *A*—Are you speaking of that prescription or the alcohol?

Q—I am speaking of the alcohol in this prescription *A*—I have already eliminated that prescription and told you that the alcohol in it produced no injury in that at all

Dr Lydston was repeatedly cross-examined concerning the action of the alcohol and the bromid in the prescription mentioned

Q—How can you say if you know nothing about viburnum prunifolium and carduus benedictus that it might not counteract the effect of alcohol as well as the bromid? *A*—I do not believe that I said that did I? Did we take that up?

Q—Didn t you state— *A*—I was asked whether I had ever used those preparations I believe, and I was asked whether those preparations would cure gonorrhea I said that preparation would not cure gonorrhea and I stated my reason

Q—Didn t you say that the amount of alcohol in there was absolutely dangerous, on account of the inflammation? *A*—I did

Q—Well then, how can you say that it would be dangerous or would not be dangerous, without knowing whether or not the viburnum prunifolium or the carduus benedictus might not act on the alcohol the same as the bromid does on your alcohol? *A*—Because bromid of potassium is a very powerful sedative a very powerful sedative and as I remember, the hypothetical question there was nothing said about this remedy being a powerful sedative. Somewhat sedative

Numerous questions were asked in relation to the hypothetical question and the amount of cnicin, carduus benedictus and viburnum in it in their relation to the alcohol

Dr Lydston testified that he has prescribed Hayden's Viburnum Compound perhaps half dozen times years ago

Q—In what case did you prescribe it? *A*—I prescribed that several times before I was advised of its composition under the inference that it contained viburnum I do not now think it does—and I am sure that it does not. I think I prescribed it in a case of ovarian neuralgia or something of that sort I prescribed it very infrequently

Q—Well you prescribed it for young girls for amenorrhea, haven't you? *A*—No I don t think I ever did

Q—Are you positive of that now? *A*—I am not sure.

Q—You won't say you have not? *A*—I don t recall it. No, I would not say I have not. No I would not say that, because I have used Hayden s Viburnum Compound on a moderate number of occasions—very little of recent years

Q—I hand you a bottle, and ask you if that is the medicine referred to? *A*—Yes that is Hayden s Viburnum Compound (Examining bottle)

Q—What is the percentage of alcohol? *A*—Fifty per cent.

Q—Without reference to whether you knew what the other ingredients were, you did know that it contained 50 per cent. of alcohol didn t you? *A*—No, I did not

Q—You did not even know that? *A*—I did not I have never seen the label of Hayden s Viburnum Compound since the Pure Food Act compelled them to put the percentage of alcohol on it.

Q—How long have you used medicines without knowing what the ingredients were? *A*—Oh I very seldom have used medicine without knowing what the ingredients were I cannot however always be absolutely certain as to a preparation and we have to take even our official remedies—we have to take them very often without absolutely investigating to see what the proportion of this and that and the other is excepting as regards the active principles

Q—Doctor are you the author of a brochure entitled 'Why the Medical Association is Going Backwards, A Critique of the Medical Trust?

Mr T J Scofield—That is objected to

Mr Hough—He has testified that he is the author of certain publications

The Court—Has this anything to do with this case?

Mr Hough—I think it has, your Honor, I think it has a good deal to do with the case.

Mr T J Scofield —It is not cross-examination, and it is utterly immaterial

Mr Hough —Can't I identify these by this witness?

Mr T J Scofield —Wait until I get through It is an effort to bring in here an immaterial issue into this case, that is entirely collateral and it would require, if there is any investigation of it, going out a good distance, far afield

Mr Hough —I should like to identify those two pamphlets by the witness (Handing pamphlets to the Court)

The Court —Yes, he may identify them I do not see at this time that they are competent

To which ruling of the Court in permitting the identification of said pamphlets, the defendants, etc, excepted

The Court —And of course it is understood that no use shall be made of the titles of those unless they are received in evidence

Mr Hough —Yes

Q —Is that the name of it? *A* —It is

Q —And you said you were the author of that? *A* —I am

(The pamphlet referred to is marked Plaintiff's Exhibit A April 24, 1916)

Q —And you are also the author of that pamphlet entitled "How Simmons, Our Peerless Leader, Became Regular"? *A* —I am

Q —Is that a copy of the brochure? *A* —It is (Having examined pamphlet)

(The pamphlet last above identified is marked Plaintiff's Exhibit B April 24, 1916)

REDIRECT EXAMINATION BY MR SCOFIELD

On redirect examination Mr Scofield asked Dr Lydston to explain the use periods of dosage, and the number of doses per day of the prescription read by Mr Hough He stated that the book was written in 1899 and the prescription ordered one dose at bed time to get the sedative effect of the bromid and hyoscyamus

TESTIMONY OF DR W W CORNAG

Dr Cornag was called as witness for the defendants

DIRECT EXAMINATION BY MR WALDO

Dr W W Cornag testified that he has been practicing medicine for twenty-six years in Lavonia Ga He has had some experience with McElree's Wine of Cardui He was called to see a Mrs J S She related that she was suffering with falling of the womb and hemorrhage pains in the pelvic organs and in the back She had been taking Wine of Cardui for about a year without relief He made a pelvic examination and found her womb down to a small extent, enlarged, and there was a slight hemorrhage that had been going on at irregular intervals He advised her to have an operation A surgeon was called and he suspected there might be cancer of the womb At the time of operation the surgeon found what he thought was the beginning of a cancer of the uterus and a small cyst of the ovary He amputated the body of the uterus and removed the cyst The woman has been in good health since

Mrs G R told the witness that her menstruation had stopped for a year and she had been gradually getting weaker She thought she had some uterine trouble and had been taking Wine of Cardui, but without relief He found that her weakness and suppression of menstruation was due to consumption The woman died of this disease about four months after he first saw her Mrs G R told him that she had taken several bottles of Wine of Cardui for about a year

Mr McW was a patient of the witness for alcoholism This patient stated that when he could not get whisky, he would drink Wine of Cardui The occurrence was seven or eight years ago The witness saw McW drink perhaps one-fourth of a bottle on one occasion

The witness stated that he was called to see Mrs Y, who was complaining of pains in the region of the uterus, with burning sensations, pains in the back, and whites On pelvic examination he found a gonorrheal infection of the womb and tubes This patient stated that she had been taking Wine of Cardui off and on and she had been ill for eighteen months He treated her for a heart disturbance The patient died about two weeks ago of pneumonia

Another patient, Mrs C R, complained of pains in the pelvic region, painful menstruation and whites He found on examination that she had a syphilitic ulcer of the mouth of the womb The patient stated that she had taken Wine of Cardui without being relieved He was able to get her in pretty good shape with specific treatment for syphilis

Another patient was F M, who complained of scanty, irregular and painful menstruation and sterility, for which she had taken Wine of Cardui, without relief On examination he found that the mouth of the womb was small—there was no diseased condition He advised her to have an operation which she refused

CROSS-EXAMINATION BY MR WALKER

On cross-examination the witness testified that he came to Chicago about four weeks ago He received a notice from the secretary of the state medical society asking if he knew anything about the use of Wine of Cardui, and later he met Dr Heizer in Atlanta, Ga The witness is a member of the American Medical Association He has not resubscribed for The Journal, which he has taken off and on at various periods He understands that his expenses will be paid and that he will receive a reasonable per diem for the time lost during his attendance in Chicago

He was repeatedly cross-examined concerning the names and addresses of his patients and he promised to give this information to the counsel for the plaintiff He was also repeatedly examined concerning the incidents described in the direct testimony

Q —Doctor, do you keep a drug store? *A* —Yes, sir

Q —At Lavonia? *A* —Yes, sir

Q —You still run it? *A* —Yes, sir

Q —How long a time have you been running a drug store? *A* —Ten years about

Q —During all the time that you were treating the patients that you have named here, you had that drug store? *A* —Yes

Q —Who is taking care of your drug store, and of your business? *A* —My daughter is in charge of it

Q —She is a pharmacist, is she? *A* —No, sir, I don't run a prescription business I run a retail 'patent medicine' and stationery business

Q —You sell 'patent medicines"? *A* —And carry my own pharmaceuticals

Q —Well, do you sell Peruna? *A* —Oh, yes, sir

Q —Lemon Extract? *A* —Yes

Q —Aletris Cordial? *A* —No, sir

Q —Hayden's Viburnum Compound? *A* —No

Q —You don't sell anything that doctors ask for on prescription? *A* —I don't fill prescriptions I am not licensed

Q —Do you carry Lydia Pinkham? *A* —Yes, sir

Q —Her remedy? *A* —Yes, sir

Q —What others? *A* —Wine of Cardui

Q —How long have you carried Wine of Cardui? *A* —Oh, about eight or nine years

Q —What others? *A* —I don't know I have got—

Q —Duffy s Pure Malt Whiskey? *A* —Sir?

Q —Duffy s Pure Malt Whiskey? *A* —No, they would not let me sell that in my town

Q —Hostetter's Bitters? *A* —No

Q —What other medicines, besides those named? *A* —I got Harder s Iron Tonic

Q —How much alcohol is in that, do you know? *A* —I do not know

Q —What else? *A* —I could not tell you, just a small line of patent medicines that people ask for mostly, that is all

Q —Do you carry any drugs yourself? *A* —I carry my pharmaceuticals, that I use in my practice

Q —What school did you graduate from? *A* —Atlanta Medical

Q —What is that, Regular? *A* —Yes

The witness was then asked questions regarding the various sects in medicine He was asked concerning the disposition of his practice while he was attending the trial in Chicago and questioned in detail concerning his treatment of Mrs Y, who suffered with gonorrhea He gave her an astringent douche, digitalis and salines He also gave her Blaud's pills He did not prescribe "Cardoseptic"

Q —You mentioned some iron remedy that you keep there, some patent or proprietary medicine? *A* —Harder s Iron Tonic

Q —Did you give her that? *A* —No sir, I don't prescribe patents

Q —How much alcohol was in that? Well, you recommend them, don't you? *A* —No, sir, I do not

Q —You just sell them? *A* —Yes, I sell them, when they ask for them

The witness was then questioned in detail concerning the case of Mrs C R, who had syphilis He treated her with mercury and iodids, and prescribed an antiseptic douche.

The witness was then asked if he recognized the signature of Mr McW He could not identify the signature

Q—He told you that when he could not get whisky, he would take anything that had it in it? *A*—He preferred Wine of Cardui

Q—Did he also tell you that he would take anything that had alcohol in it? *A*—Well, he said he had to have alcohol

Q—Did he buy it of you? *A*—Yes he did

Q—Over what length of time had be bought Wine of Cardui from you? *A*—He was the first man that ever I knew of buying a bottle in my place for intoxicating purposes and right then I instructed my clerk not to sell him any more

Q—When did he first buy Wine of Cardui from you? *A*—It was about seven years ago

Q—You say be bought it then for intoxicating purposes? *A*—He did

Q—How did you know that? *A*—He told me he did

Q—Did he drink it there in your store? *A*—No he drank it in his room

Q—Is that the occasion that you saw him drink a quarter of a bottle? *A*—Yes

Q—How much did he buy? *A*—That one bottle, is all I can testify to

Q—Had he bought Wine of Cardui before? *A*—I think he had

Q—Is that the reason that you think—that is the first time you knew he bought it to drink himself? *A*—It is the first time I knew anybody was using it for that purpose in my community

Q—How long had you carried it then? *A*—I had carried it about three years

Q—When was the last time you sold McW any? *A*—That was the last time I think

Q—Has McW ever purchased any for his wife or daughter? *A*—He has not got a wife

Q—Has he got a daughter? *A*—No sir never has been married

Q—Does he live with his sisters? *A*—No he was boarding at a *hotel*

Q—A hotel in the town where you are? *A*—Yes

Q—What hotel? *A*—The Lavonia Hotel

Q—Did you have a clerk at your store? *A*—Yes sir

Q—Other than your daughter? *A*—Yes sir

Q—Seven years ago? *A*—Yes sir

Q—Who? *A*—J T Holland

Q—How long did he work for you? *A*—He worked for me about three or four years

Q—When did he quit? *A*—About a year ago is the last time he has been with *me*

Q—What is his full name? *A*—John T Holland

Q—Where does he live? *A*—At Lavonia

Q—Is he there now? *A*—He is the man that sold McW this bottle of Wine of Cardui He asked McW why he was buying it and he says—

Q—There is no question pending Did you see McW drink that bottle? *A*—Yes he drank part of it

Q—Were you there when he drank it—when he bought it? *A*—No

Q—Well did this clerk that was working for you see him drink it? *A*—No sir

Q—How did you come to see him drink it? *A*—I was called out to his room that evening

Q—At the hotel? *A*—Yes sir

Q—And you went over to the hotel? *A*—Yes sir

Q—Who told you the conversation that he had between the clerk—*A*—The clerk

Q—Well what was it he said? *A*—I asked the clerk if he had not made a mistake in charging it wasn t it a mistake about him getting that bottle of Wine of Cardui I saw it on the book there and he says No he come in here and went behind the counter and looked around the shelves and he pulled down a bottle of Wine of Cardui and told me to charge it to him I asked him what he was buying that stuff for and he says I am buying it because it has got more alcohol in it than anything on that shelf' That is what the clerk told me

The witness stated that he sold about eighteen bottles of Wine of Cardui a year

Whereupon the further hearing of the case was adjourned until 2 o clock the same day

April 24, 1916, Afternoon

TESTIMONY OF DR. ALONZO C TENNEY

Dr Alonzo C Tenney was called as a witness for the defendant

DIRECT EXAMINATION BY MR T J SCOFIELD

Dr Tenney testified that he is a practicing physician residing in Chicago He graduated at the Hahnemann Medical College in 1895 He is a homeopathic practitioner After graduation, he spent a year as intern at the Hahnemann Hospital He is a member of many homeopathic medical societies and has held office in practically all of them He has done postgraduate work at the University of Chicago, the Chicago Clinical School, the Chicago School of Electro-Therapeutics, the Graduate School of Harvard University and the New York Postgraduate School

Q—Doctor, will you explain what are the fundamental principles of the law of similars, the homeopathic law, as I understand it, of drugs and cure? *A*—I did not quite get the first part of that question

Q—Doctor what are the fundamental principles of the law of similars? *A*—The homeopathic practice is based upon what we call the law of similars That law is exemplified in this way We give the drug that we want to learn about to a healthy human being This healthy human being we call a prover And the conditions which are produced in his body or her body as the result of the administration of a drug, we call a proving These provings are shown by symptoms, or they are results recorded by symptoms changes in the feelings and condition of the prover that is our guide to the administration of a drug When we find in a sick person a set of symptoms produced by a disease which are the parallel of a set of symptoms which we have produced artificially by the administration of some drug we think of that drug as the one which will produce changes in the patient s body leading to recovery Now, in proving our drug we give material doses that is we give big doses. We begin carefully and keep on increasing and increasing the dose, always being careful not to poison the person fatally This work has not been done much of recent years

But when we come to prescribe for a sick person we do not use a large quantity of the drug We use very small quantities And now here is a second point in our belief A drug may be so altered we believe by dilution, by attenuation by grinding up with sugar of milk or diluted with alcohol and water to such an extent that its molecular parts are separated and that the chemical affinities which exist in that drug become active in the human body to cure disease A more recent method of describing this process is to refer to what is known as the ionic theory but that is a rather complicated thing and I do not think it is necessary

Q—All right Doctor are you familiar with the homeopathic method for prescribing viburnum prunifolium? *A*—No I am not

Q—Why not, Doctor? *A*—Because viburnum prunifolium has never been proven It has never been tested on a healthy human body, and there can be no homeopathic basis without this preliminary knowledge of the drug s action

Q—Then you are not familiar with the indications for that drug? *A*—No there are no homeopathic indications for it It has never been proven

Q—Now in your experience of 20 years or more in the practice of medicine have you ever used viburnum prunifolium? *A*—Yes, I have used it empirically on the ground given me when I was a student.

Q—To what extent have you used it Doctor? *A*—Well when I first began practicing over 20 years ago I used it quite frequently It was then given in the books on materia medica as a drug for certain ailments with which women were suffering I used it repeatedly I had no results from it It proved absolutely worthless in my hands and very unfortunately so

Q—Doctor are you familiar with the homeopathic method of prescribing cnicus benedictus? *A*—Yes I am

Q—Upon what are these indications based? *A*—They are based upon the provings of cnicus benedictus

Q—Well are you familiar with what you call the provings the homeopathic provings of cnicus benedictus? *A*—Yes I am familiar with those provings.

Q—Now what do those provings show Doctor with reference to the effect of the drug upon the reproductive organs of the female? *A*—It shows no effect upon the pelvic organs at all

Q—Well then, what are your conclusions with reference to the clinical value of this drug in the treatment of pelvic diseases of women? *A*—My conclusions are that the provings of this drug do not point to them at all, and that it could have no basis in homeopathy whatever for prescription in that condition in that class of diseases or ailments pelvic troubles

Q—Doctor according to the homeopathic theory of medicine should drugs ever be used in combination? *A*—No we give according to our strict homeopathic theory only one drug at *a time*

Q—Now take these two drugs which I have mentioned namely viburnum and cnicus benedictus and suppose these drugs are used in doses of approximately three grains of the extractives from the bark of viburnum prunifolium, and the extractives from approximately 30 grains of cnicus benedictus and that they are *combined in these* proportions with 48 drops of alcohol to each dose of a tablespoonful in your opinion could such a combination be used for the treatment of pelvic disorders of women on the homeopathic theory of practice? *A*—No absolutely not on the homeopathic theory

Q—Now explain why *A*—Well to begin with we have no proving of one of them so we do not know what is its field of action In the second place we are given drugs in combination and even if we credit these two drugs with the virtues which in some instances they are supposed to have their field of action is different one affects *one* set of organs the other if it affects anything affects another set of organs There would be no excuse according to our homeopathic theory and practice and experience to combine these drugs. In the *third place* they are made with a twenty per cent alcohol as I understand the question Now our homeopathic tinctures are made with a much stronger amount of alcohol they are made with the strongest alcohol used in ordinary pharmaceutical work running 93 per cent. by weight and 98 per cent. by volume pure alcohol That alcohol with our homeopathic tinctures will extract resins and other alcoholic extract Therefore, our provings of cnicus benedictus would be provings of an entirely different substance from a 20 per cent alcoholic extract of cnicus benedictus It would have things in it which would not and could not by any stretch of the imagination be in this hypothetical solution

The homeopathic method of prescribing is different. We use the drug in attenuations. The dose here would be altogether too large to have any of the therapeutic effects which we expect to get by the administration of our drugs homeopathically And it occurs to me that there would be serious doubt whether the dose is large enough to have the physiologic effect which we sometimes endeavor to get. So on every count there is no possible application of this substance you have described in homeopathic practice

Q—Now, Doctor, you have stated that on the strict theory of homeopathic practice medicines are not given in combination In actual practice do conditions ever arise under which you do prescribe drugs in combination? *A*—Yes, such conditions do arise

Q—Explain why and under what circumstances? *A*—Sometimes we want to physic a patient, we want to stimulate the kidneys, we want to quiet the nervous system Take a physic, for instance, to illustrate the point We might use what is prepared by our homeopathic pharmacists for that purpose a combination of two or three or four drugs, all of which act upon the liver of the intestines and the liver, but using small doses of each individual drug so as to avoid any of its poisonous effects and combining it with other drugs acting upon the same organ or related organs to get nothing but the stimulative, laxative effect In that way we may use drugs in combination

The witness was then asked a hypothetical question similar to that asked of previous witnesses and he stated that he had an opinion as to the physiologic action and therapeutic value of the hypothetical medicine on the homeopathic theory of practice He stated that there was no foundation whatever for this hypothetic prescription

Q—Well, now, a little more in detail Doctor In what way, Doctor, does it fail to comply with the principles of homeopathy? *A*—It is not a tincture, to begin with It is not a homeopathic tincture There is a 20 per cent solution, 20 per cent alcoholic extract of the drug prescribed in it—or of these two drugs There are two drugs combined, which is antagonistic to the homeopathic practice There is no proving The dose is too large for the homeopathic effect and even if we credit the cnicus benedictus here with having the same effect as we would if it were a homeopathic tincture, it is faulty because it is a combination of two drugs at the same time, and as I have already said, the tincture derived homeopathically by the homeopathic pharmacist would be an entirely different substance from that described here

Dr Tenney stated that the hypothetic medicine could not affect gonorrhea either in acting on the germ or through any action on the tissues of the body He stated that it would not have any effect on uterine prolapse nor would it cure retroversion or retroflexion nor sterility nor menorrhagia nor metrorrhagia

A—In dysmenorrhea there could be no effect on any of the causes which I have in mind for dysmenorrhea except possibly the effect of the alcohol, the same as when a patient takes a little hot gin for a painful menstrual period, something of that sort.

The hypothetic medicine, he stated, would not cure amenorrhea and there is no occasion for its use in puberty or in pregnancy Such a medicine could not be used according to the homeopathic school as no routine prescriptions are used by that school Dr Tenney described the method of preparing homeopathic tinctures

CROSS-EXAMINATION BY MR HOUGH

On cross-examaniation, Dr Tenney stated that in a dosage of 5 drops of alcohol and one one-thousandth part of viburnum, the dose would be given perhaps at intervals of fifteen minutes for one hour or two and then gradually lengthening the interval to two hours, three hours, etc, but it is not practicable to give such large doses The effect of those doses would be that of alcohol only as though no viburnum was present He stated that the fact of a drug appearing in the homeopathic pharmacopeia means that the druggist has it to sell The publication of the drug does not mean that it has been proven He described the use of the homeopathic pharmacopeia of 1914 and stated that like himself, the great majority of homeopathic physicians with whom he is acquainted have discarded viburnum prunifolium He has prescribed carduus benedictus a few times and it gave no good results, so he discontinued its use In place of carduus benedictus he uses mercurius corrosivus, mercurius dulcis, mercurius iodatus There is no alcohol in these preparations They are reduced to the third X with sugar of milk Among other remedies which contain alcohol he uses gelsemium, bryonia, chelidonium Lycopodium which he gives is prepared in powder

The witness stated that he has never made provings of any drug, if the drug is mentioned in a textbook, appeals to him, he tries it

Q—Well, to commence with, all you know about it is what your literature, that is, homeopathic literature, shows to have been proven, don't you? *A*—Well, the literature does not always show things to have been proven, you know Because a thing is written don't make it so

Q—You mean the book of provings in the homeopathic school is not accepted by you? *A*—Oh, no, I don't mean that. You must understand these provers were people who made their living to a very great extent, by proving, and some of them were very profoundly affected by the drugs they took Some of them were rendered sick and remained so the remaining portion of their lives Now these people sometimes did not recognize the fact that the effect of a drug like mercury or iodin or arsenic had not passed off, and they would be proving another drug and reading into the provings out of their own ignorance—possibly of the man who was employing them at that time—they would be reading into the provings these provings of the previous drug possibly, so that our old provings, although we regard them with a great deal of respect, and take them with a great deal of consideration, are not, in the light of our modern knowledge to be relied upon absolutely And that is the consensus of the homeopathic physicians who are up to date today

The witness stated that he had not heard of anyone using viburnum prunifolium in cases of threatened miscarriage The witness testified that according to his present knowledge, viburnum prunifolium was not used for a number of complications mentioned by Mr Hough He stated that carduus benedictus had been proven but this does not mean that it was not inert There are several hundred drugs in the homeopathic pharmacopeia and there are others besides viburnum prunifolium and carduus benedictus which are inert. Asked to mention some, he stated

A—Well, I will give you a few examples, but to go through the whole pharmacopeia, I am not competent to do But there is an instance Somebody made a proving of the effect of the steel taken from the north pole of the horseshoe magnet This fellow was a long haired enthusiast, in my opinion, those who know anything about him or his provings or the things he claimed for that drug do not pay any attention to it In regard to viburnum prunifolium, there has been no proving of it We disregard that And as to cnicus benedictus, I think that the majority of us know that it has no effect And in regard to—

Q—I am asking you about something that is in the pharmacopeia Aren't you naming something that is not in the pharmacopeia? *A*—Well, I don't know as to that I am thinking of the things that have been discarded by the majority of us

Q—Well, I am not asking about anything that has been discarded and is not in the pharmacopeia *A*—Now, there is sugar of milk that is in the pharmacopeia I think somebody made a proving of sugar of milk once You see we have enthusiasts in all walks of life and some of them have brought the homeopathic school into disrepute which we very much regret

Q—I don't see it here *A*—All right Possibly you had better let me have the book, and look through it for a few of those drugs I cannot recall them off hand

Q—Sugar of lead is the only one in fact— *A*—Sugar of lead would be an active drug

Q—You spoke of sugar of milk which I don't see there (Handing book to witness) *A*—Carbo vegetablis vegetable carbon We will call that out of the active drugs

Q—Well, is that sugar of milk? *A*—That is vegetable carbon, charcoal

Q—I say, is that sugar of milk? *A*—No, it is not I have answered that.

Q—You don't find sugar of milk there? *A*—I have not looked for it. You said it was not there, and I took your word for it. We will look for saccharum lactis, that is the homeopathic name for sugar of milk I don't find sugar of milk

Dr Tenney was then asked concerning extracting of drugs with alcohol He recognized that there is such a thing as synergism He is not a member of the American Medical Association unless some of his connections automatically make him a member He is a subscriber to The Journal and is a member of the Chicago Medical Society He was then cross-examined in detail concerning assumptions in the hypothetic question

He was then asked to state in brief his method of treatment of gonorrhea He gives an antiseptic douche and by mouth he gives laxatives, also iron or any tonic which may be necessary, and advises the patient to avoid exercises, alcohol and coffee. He put her on a simple nutritious diet He usually gives iron hypodermically

Q—Is there any alcohol in the tonics you give? *A*—In any of the tonics that I give in gonorrhea you mean?

Q—Yes *A*—Not that I know of I try to avoid all alcoholics in my remedies

Q—What do you mean by "not that you know of?" *A*—Well here is the idea Once in a while some detail man comes along from Parke Davis & Company and says Doctor, here it is at last He will leave a sample bottle and later when I am in a hurry some people will come in with a condition he has just described, and you will say How fortunate that is here is a patient here that we have just been told how this medicine will act on him' And we give him that and possible find out the next day that it contains alcohol May be it is a good remedy and may be it is not That sort of thing of course is not in accord with the kind of work which we aim to do all the time But those are the circumstances when these little things creep in under your guard as it were

Q—But you know how much alcohol is in it at the time you prescribe it don't you? *A*—Well we do now if we prescribe those things because the pure food and drug law has been in operation—

Q—And you have known it since 1906? *A*—Well, with that correction I should say I never prescribe alcoholics without knowing it since 1906

Dr Tenney was asked concerning his treatment of prolapse of the uterus He described the various degrees of prolapse and mentioned the treatment He mentioned certain cases of sterility which might be cured by medical measures for example obesity as a case may be cured by thyroid extract, anemia by administration of iron and arsenic, etc He would treat stenosis of the cervix by surgical or mechanical means He described stenosis of the cervix and its complications and the method of treatment In treating dysmenorrhea he would give something to relieve the pain He could not think of a single case of stenosis which would not be benefited by an operation He was asked as to the treatment of hematometra He would give ergot or pituitrin and perhaps pack to prevent bleeding

Q—You mean you would use a uterine medicine? *A*—A uterine medicine?

Q—Yes *A*—Well as homeopaths we don't know uterine medicine We use some remedies that act upon the womb like pituitrin for instance or ergot but they act upon all parts of the unstriped muscle tissue equally as such

Q—Those are allopathic remedies? *A*—No no they belong to any physician who wants to use them They are not allopathic There is no such thing as allopathic any more

Q—What do you call it now? *A*—Well we have the—we are physicians There are a few who still cling to certain of their homeopathic belief *and homeopathic practice and so we sometimes are men*tioned or spoken of as homeopathic physicians but we don't—we *don't divide the thing up into a lot of wrangling sects*

THE COURT—You mean that nobody is so bigoted today that he is unwilling to make use of somebody else's medicines if he believes it is best for the particular disorder that he has in charge?

The Witness—That ought to be published Your Honor that is very excellent

Mr Hough *Q*—Well when you say you don't know any such thing as uterine medicine you are speaking as—not as an allopath but as a homeopath? *A*—No sir I am speaking as a physician I don't recognize anything as being especially a uterine medicine There are certain medicines which act upon the uterus more apparently than they do upon other tissues because the uterus is the biggest mass outside of the heart of unstriped muscle tissue in the body And ergot contracts unstriped muscle everywhere It blanches the fingers the nose the ears the tongue the lips and it contracts the uterus Why does it blanch these parts? Because it contracts the unstriped muscle tissue in the arterial vessels And it contracts the unstriped muscle tissue of the womb It is a remedy which acts upon the whole circulatory apparatus The same is true of pituitrin the same is true of adrenalin chlorid The same is true in a lesser degree of hydrastis or hydrastinin

Q—Any others you can think of? *A*—Those are the drugs upon which I depend more especially I will mention another eserin sulphate has that effect

Q—Did you ever use apiol? *A*—Apiol?

Q—Yes *A*—*Yes I have used it It is a French preparation that* has failed me

Q—Failed you? *A*—*Yes it has not given the results it was sup*posed to give

Dr Tenney was asked concerning his treatment of amenorrhea, he stated that if due to anemia he would give iron arsenic, and quinin, if tuberculous, he would use outdoor treatment and diet, if stenosis, he would operate on the stenosis, if chlorosis, he would give iron, arsenic and an extract of bone marrow, if due to obesity, he would treat obesity He would treat amenorrhea as a symptom

Q—Don't you prescribe according to the symptoms? *A*—And we treat the underlying cause back of this symptom in order to correct the *symptom*

Q—Don't you prescribe according to symptoms? Isn't that homeopathy? *A*—Well yes—you know—I think the best illustration of the difference in the line of attack of the homeopathic physicians and the rest of the medical world may be well illustrated in this way You go to church and you hear the minister preach about Noah building the ark One minister begins with Noah and another begins with the Ark and tells all about it but they are both talking about the same subject In some things homeopathy starts after the symptoms *first* but we are always looking for the underlying cause trying to relieve that otherwise we would not be able to hold our heads up in this modern world The old school men very frequently start right after the diagnosis and explain the symptoms from their diagnosis But we are all working to the same end

Q—Well the practice of homeopathy teaches the prescribing for the symptom doesn't it? *A*—Well the original teachings yes You must remember that the progress of medicine in the last fifty years has been very great—

Q—Well are you practicing homeopathy now? *A*—I am practicing homeopathy plus *I am practicing medicine and I use my homeo*pathic remedies, my homeopathic philosophy and my homeopathic lines of procedure, where they do good *for my patients Where they don't* do good I discard them

Dr Tenney testified as to drugs mentioned in the homeopathic pharmacopeia for the treatment of amenorrhea and as to the quantities of alcohol in these preparations He stated that alcohol would have no effect on the condition

Q—Did I understand you to say that pregnancy is not a pathological condition? *A*—Certainly you did understand me to say that if I have been asked that question Pregnancy is a normal condition—if it is a *normal pregnancy*

Q—And therefore would not be considered pathological? *A*—Certainly not

Q—But purely physiological? *A*—Purely physiological

Q—Did you hear Dr De Lee's testimony? Were you in court? *A*—I heard a portion of it

Q—You disagree with him?

Mr T J Scofield—If the Court please—

THE COURT—He said the same thing

Mr T J Scofield—Dr DeLee said the same thing

THE COURT—He said an absolutely normal case was not pathological

Mr Hough—I did not ask him about an absolutely normal case

THE COURT—That is what this witness said He said the normal pregnancy is physiological

Mr Hough—I asked him if pregnancy is pathological—is it ever pathological?

The Witness—You asked me if a normal pregnancy was a diseased condition or something of that kind

Mr Hough—I did not use the word normal

The Witness—A normal pregnancy is normal

Mr Hough—Of course

The Witness—Yes

Mr Hough *Q*—If it is pathological—

The Witness—A pathological pregnancy is pathological

The witness then mentioned some of the complications of pregnancy He described the care of a patient in a pregnant condition If patients require tonics he usually gives them in powdered form without alcohol

Q—How long have you been *giving medicine without alcohol* since this case started? *A*—No no indeed I have not even—I don't think *about the amount of alcohol*—I just did that to save you the trouble of asking me how much alcohol there was in it.

Q—*You mean you never give any medicine* you think there is any alcohol in in any of those conditions? *A*—No no—I might give something containing alcohol *Some of them I prescribe alcohol* for but that is very rare

Whereupon the hearing of the above case was adjourned until Wednesday *April 26 1916*, at *10 30* o'clock a m

April 25, 1916, Morning

The Court met pursuant to adjournment On motion by Mr Walker, who informed the Court of the death of one of the plaintiffs, the Court was adjourned until Tuesday, May *2*

May 2, 1916, Morning

The Court met pursuant to adjournment Mr Walker informed the Court of the death of the plaintiff, Mr John A Patten and stated that it was desired to proceed in the partnership case

The Work of the Young—The fact that young persons' fingers are nimble and their actions quick should not be taken advantage of by allowing disastrous exhaustion to lessen their vitality at this most important period of life Particularly does this apply to the permitting of piece-work, and monotonous or steady straining processes—*Hayhurst*

Correspondence

What Is a Vitamin?

To the Editor —The following statements I wish to make in justification of my position as the author of the term "vitamin" as well as in refutation of some of the statements printed in your editorial entitled "What is a Vitamin?" (THE JOURNAL, May 6, 1916, p 1470) I have no doubt that the sense of justice and fairness which have always impressed me in your publication will guide you to publish my letter in an early issue of THE JOURNAL

When early in 1911 I started the research which led to the isolation of the vitamin-fraction from various foodstuffs, my work was inspired by the remarkable results of Eijkman Grijns and Schaumann, who were able to prove that in rice-polishings and in yeast, substances are present which protect fowls, pigeons and men against beriberi My task was then to find out to which chemical group these protective substances belong and this has been successfully accomplished and described in two publications (*Lancet*, London, Nov 4, 1911, *Jour Physiol*, Dec 22, 1911) From reasons unknown to me, references to these two early publications are usually omitted in the literature, and the paper of Hopkins (*Jour Physiol*, 1912, xliv, 425) is quoted, which has been undoubtedly partially influenced by my work It was only in 1912 (*Jour State Med*, June, 1912) after a careful revision of my experimental data that I introduced the term "vitamin" for these protective substances which are indispensable for life and which, judging from their chemical reactions, belong undoubtedly to the group of organic nitrogenous bases Later on I went farther, and a few substances were isolated and analyzed which, I have reasons to believe, are chemically related to the original vitamin present in less purified fractions I am glad to say that even now, after five years, there is not a single paper in the existing literature able to refute my experimental data That the introduction of the term "vitamin" was justified we can judge from the quick succession of terms used to designate the same substances torulin of Moore, Oryzanin of Suzuki, antiberiberin of Tsuzuki, accessory substances of Hopkins, and finally substances A and B of McCollum If terms could only be applied to chemically pure, fully identified substances, 90 per cent of the already existing names in the physiologic chemistry would have been discontinued (examples names of ferments, hormones, proteins, nucleins, polysaccharids, lipoids, cerebrosids, etc)

As to the necessity of two different substances (one soluble in alcohol and the other in water) for growth of young animals, the work done in conjunction with A B Macallum was not able to substantiate it Vitamin is soluble in alcohol and more so in water, but we are dealing here with one and the same substance Our present results so far show that the beriberi-vitamin suffices for growth of young rats, for long maintenance (over sixty days) a small supply of antiscorbutic vitamin seems necessary, otherwise scurvy with even slight rachitic symptoms occurs in rats This condition can be avoided by using autolyzed (wet) yeast or orange juice, in difference to dried yeast, which apparently possesses no antiscorbutic properties for rats So far in our experiments butter was found to have no action on the growth of rats, but was found to have slight antiscorbutic effect (scurvy-vitamin carried down from milk) In order to avoid further complications and fallacies in the already complicated problem of growth in rats, we wish to test our preliminary results in all directions before final publication, but we find that some of the recent results on the growth of rats, on which your editorial is based, give not the slightest justification for the discontinuation of the term "vitamin"

In the same issue of THE JOURNAL, Dr E J Wood deals with pellagra as being due to a deficiency of vitamin Apparently by mistake my name was omitted as the originator of this hypothesis (*Jour State Med*, June, 1912, "Die Vitamine," Wiesbaden, 1914) Later on I pointed out (*Jour Physiol*, December, 1913, *Munchen med Wchnschr*, 1914, No 13) that the acute form of pellagra prevailing in the United States might be due to the use of extensively milled corn, to which conclusion Dr Wood also arrives

Teaching Units and Mergers of Medical Colleges

To the Editor —I have read the Current Comment on this subject (THE JOURNAL, May 6, 1916, p 1471) with much interest It points the direction that medical education will have to take, but a word of warning should be sounded lest a fetish be made of the word "university," and weak medical schools be linked together without having real university methods and equipment Medical teaching cannot be improved until the unit system is established in the clinical as well as in the laboratory branches How many universities have put their clinical teaching on a university basis? How many provide their professors in the clinical branches either directly or indirectly with hospital wards, dispensaries and laboratories? How many are prepared to meet the university ideal that a professor in a clinical branch shall have an active service of at least sixty beds and shall not attempt to give bedside instruction to more than a proportion of one student to three beds? Here is where the application of the unit system is needed The old idea that there should be but one professor, *the* professor, must go A university must increase its units in the clinical branches because of the very nature of things A professor cannot *properly* look after more than sixty bed patients, and a patient can be observed and studied by only a few students at the same time and then only once in a day It is this feature that makes proper medical education so costly In dealing with inanimate objects, the same apparatus and equipment can be used over and over again even on the same day, but, of course, patients cannot be so used

By all means let us have university control of medical schools, but let us be sure that the university will assume the same degree of responsibility in teaching the clinical branches that it does in teaching the other sciences Let us make sure that universities are not used as a cover for concealing inadequacies in financial resources or control of clinical material

OWNERSHIP OF ROENTGENOGRAMS

To the Editor —I am writing to inquire whether or not there has been at any time a court decision with regard to the ownership of roentgenograms As a rule, there are three claimants, each presenting arguments which to him seem conclusive, namely, the roentgenologist the physician and the patient The situation has been a nuisance to several of us in this community at various times

A B DIEPENBROCK, M D, Sacramento, Calif

ANSWER.—We can find no cases touching directly on this subject A few cases have been found in regard to the ownership of photographic plates, but even these are indefinite and uncertain in their meaning

As regards photographic plates the courts have recognized the fact that authorship and originality of intellectual creation have the right to protection This gives a photographer the right to have ideas, as exemplified by photography, protected by law But this position of the courts does not import that a photographer has any title in the plates per se His title is in the concept with some exceptions Whatever title a photographer may have in a photographic plate depends on the contractual relation between himself and the subject of the picture When a person sits for a photograph he does not usually vest the photographer with the right to use the plate as he may see fit The same, broadly speaking may also be said of a person who permits a roentgenogram to be made of his body The idea and method of posing belongs to the operator and the title of the plate in the absence of a special contract at least so far as the absolute disposition is concerned belongs to the patient The physician would not be prevented probably from using the plate for clinical purposes or lectures if the *name* of the patient was not disclosed as the plate, unlike a photograph can be recognized and understood only by experts The layman would not know to whom the plate had reference The courts have held *that persons may enjoin* the use of their photographic likeness by a photographer when such use may cause them injury

Similarly a court might enjoin the use of a roentgenogram by a roentgenologist who made it or the physician for whom it was made when the physician's agreement with the patient was that the plate was to be used for diagnostic purposes only But if it was generally understood that the patient permitted the roentgenogram to be made for such diagnostic and other purposes as the physician may see fit, then there is for all practical purposes a vesting of title or at least user in the physician This would not however give the roentgenologist title other than to the concept unless he has a special contract with the physician, as he is in no way privy to the contract between the physician and the patient The argument that the patient is not paying for the plate but only for the benefit he may derive from that method of diagnosis would go the length only of supporting a right to possession in the person making the plate supposing his contract with the physician for whom the case is being diagnosed would permit such a construction and would not give either the roentgenologist or the physician the right to use the plate in any way either might see fit It may be true that the patient cannot demand and obtain possession of the plate, but neither can the operator or the physician have an unlimited user In reality, therefore there is a joint ownership the operator depending on his contract with the physician having perhaps the general right to protection for the concept, the physician who diagnosed the case having a right of possession with a *limited* user as per contract *with the patient, and the patient* having a supervisory interest in the plate

Milk-Borne Typhoid Fever at Northbridge —An epidemic of typhoid fever in Northbridge illustrates the necessity for caution in making an epidemiological diagnosis Polluted river water was regularly introduced into the town mains for fire purposes A history of a fire within the period of incubation of typhoid fever, plus the wide distribution of cases, pointed to water as the carrier of the infection Yet careful analysis of the milk supply accounted for every case Sixteen out of the twenty-two patients received milk from a dairy in which a milker and pedler was discovered ill with ambulatory typhoid, confirmed by Widal and examination of urine and stools Even the six cases not receiving milk directly from the infected dairy had been subjected to the infection by the exchange of milk These cases developed too soon to have been secondary infections —*Public Health Bulletin* Mass State Dept of Health, March, 1916

Liability of a Railroad Company for Malpractice

(Boring v. Chicago & Erie Railroad Co. (Ind.), 110 N. E. R. 545)

The Supreme Court of Indiana reverses a judgment sustaining a demurrer interposed by the railroad company to a complaint seeking damages for the death of an employee alleged not to have been properly treated after he fell from a hand car and struck his head on one of the rails of the track, thereby suffering a rupture of a blood vessel in his head from the effects of which he died on the following day. The court says that it is well settled that a railroad company is not liable to an injured employee for the negligence of a physician called by it to render medical or surgical aid, if it was not negligent in selecting and employing an incompetent and unskilled physician. If, however, the company knowingly selects an unskilled and incompetent surgeon, a different rule applies, for his negligence then becomes the negligence of the company and it is responsible for resulting injury. The complaint in this case charged that the injury stated caused the employee to become unconscious and thereby rendered him unable to provide for and take care of himself in the emergency, whence it became the duty of the company to take care of and provide him with competent medical care and services; that with full knowledge of all the facts the company selected an incompetent and unskilled physician to treat him, and that by reason of the negligence of the physician he failed to recover from his injuries; that the physician permitted him to go to his shanty, in which he was living, alone and unattended, and permitted him to stay there over night and through the next day without any medical attention whatsoever; that the company well knew, or by the means of exercising reasonable care and diligence could have known, that the accident to the skull would cause a rupture of the blood vessel and cause death by pressure on the brain, etc. The facts alleged in the complaint must be treated as admitted as against the demurrer and, if sustained by proof, were sufficient to warrant a finding on the part of a jury that the circumstances surrounding the injury occasioned an emergency in which it became the duty of the company to take reasonable steps to prevent an aggravation of the man's injuries through exposure or neglect. It is held further that the complaint sufficiently charged negligence on the part of the company, and that the trial court erred in sustaining the demurrer to it.

Validity of Rat-Proofing Ordinance to Prevent Spreading of Bubonic Plague

(City of New Orleans v. Sanford et al. (La.), 69 So. R. 35)

The supreme court sets aside a judgment of conviction for violation of Ordinance 17 as amended by Ordinance 21 of the Board of Health of the city of New Orleans and Parish of Orleans, or the rat-proofing ordinance adopted as a precautionary measure against bubonic plague. The ordinance was held invalid on the ground that some of its provisions were illegal and oppressive. The ordinance was assailed on the ground of its unreasonableness. It professed to be a measure for protection against rats by destroying their harboring places while it was, in the nature of things, inoperative as against certain state and federal government buildings and structures, which were admittedly the main source of danger. This included, also, the garbage dumps, which were admittedly the common resort of rats. The city did not rat-proof these foci of infection, because there were no funds available for the work. The ordinance thus compelled the property owners to rat-proof their premises, whether or not they had the funds to do it with, while those public foci of infection, the most dangerous, were left in full operation, scattered as they were throughout the city. This was claimed to be an unreasonable exercise of the police power, especially when attended with so great expense, and in many cases at so great personal sacrifice. A police measure dictated by some evil to be remedied should be commensurate with the necessities of the occasion. Where the same feature which operates as a public menace is present in all premises alike, the police measure for correcting this feature should operate as against all premises alike or else against none. And the public is no exception to this rule. But if, as the evidence in this case showed, this rat-proofing, coupled with rat-catching, was the only practicable mode of fighting the spread of this disease, and if, as was the case, the board of health was powerless to make this mode compulsory either against the federal, the state or the city government, what was it to do? However oppressive, however discriminating, however unreasonable this ordinance apparently might be, there was nothing else for the board of health to do, under the circumstances, than to adopt it, and hence the adoption of it was justified. But it stood to reason that the peaceful homes and business places of the inhabitants of this large city, constructed in conformity with the rules and regulations theretofore prescribed by the public authorities, could not be, overnight, by a stroke of the pen, converted into unlawful structures, so that such inhabitants, on reading their morning paper containing the promulgation of the ordinance, would be liable to a fine and to imprisonment for every day they continued to live in or own said structures. Moreover, while the board of health, or the city council, might validly clothe the health officer with the authority to ascertain and determine whether any particular building fell into the one prescribed class or the other, as, for example, the class to be concreted, or that to be merely tar-cindered, it could not invest him with authority to withdraw any particular building from the one class and place it in the other. The board of health could not delegate to a subordinate the power to create exceptions to any rule it had established, or, which was the same thing, the power to stay the operation of any rule in cases falling within the terms of its ordinances.

Restriction of Evidence to Charge of Malpractice—Giving Eggs and Toast Too Soon

(Ennis v. Banks et ux. (Wash.) 152 Pac. R. 1037)

The Supreme Court of Washington reverses a judgment obtained by the plaintiff for alleged malpractice in the treatment of her husband during an attack of typhoid fever, which resulted in his death. The court says that Dr. Banks was charged with having negligently, carelessly and unskilfully directed, prescribed and commanded that the patient be given a diet of poached eggs and toasted bread, after which he became very sick and suffered great pain and his bowels were perforated and torn. Having charged said defendant with a specific act of negligence the plaintiff might not under that charge introduce evidence of other acts, and attempt to show negligence therein, and have the jury instructed to find for her if they found that the defendant failed in any respect to exercise the degree of ability, skill and judgment ordinarily possessed and exercised by members of the medical profession practicing in his own and similar localities. The evidence should have been restricted to that tending to prove that the giving of a toast and egg diet was in this particular case unskilful and negligent treatment, and the jury should have been instructed to find for the plaintiff only if they so determined. While this rule would permit the plaintiff to introduce evidence of the defendant's treatment of her husband prior to the giving of the toast and egg diet, it would permit such evidence only for the purpose of showing that the diet given was improper in his condition at that time. Testimony given by the nurse as to the length of a rubber tube used in giving enemas, and by the plaintiff as to the heart action of her husband, had no bearing on the issue to be determined and could only have been confusing to the jury and should therefore have been excluded. The defendant urged that the trial court should have granted his motion for a nonsuit at the close of the plaintiff's case. There was evidence, however, that the toast and egg diet was, under the circumstances, an improper treatment. A physician so testified. This was evidence that the specific act alleged was negligent, and this evidence should have been submitted to the jury under proper instructions.

Meeting held April 20, 1916

The President, DR WALTER B JAMES, in the Chair

Vitamins a New Factor in Nutrition

DR CASIMIR FUNK Besides the ordinary food constituents, such as proteins, fats, carbohydrates, lipoids and inorganic salts, to which the value of our food is due, a number of substances can be found in small quantities which are as indispensable to life as the former constituents These substances I have designated "vitamins," and the diseases which arise from their lack as deficiency diseases or 'avitaminoses" I am surprised that the introduction of this term has aroused animosity since it is quite customary to give a name to a substance the presence of which is merely assumed before its actual isolation, and such terms are usually accepted until further evidence disproves their presence The evidence of the existence of the vitamins is many times stronger than in most cases in which similar terms have been introduced There is some difficulty in fractionating and identifying substances obtained in such small quantities, the vitamins, however, are sometimes stable at higher temperatures in the presence of acids, and can be thrown down by phosphotungstic acid or analogous reagents which are so largely used for the isolation of nitrogenous substances, and afterward it can be fractionated by means of mercuric chlorid and silver nitrate and baryta This precipitation is specific for vitamins, other precipitating agents which carry down heavy precipitates do not carry down the vitamins

With reference to the action of the vitamins in the tissues, nothing definite is known, except that they bear a certain relation to carbohydrate metabolism If a pigeon is fed on polished rice, it is possible to tell approximately when the symptoms of beriberi will appear when a given quantity of rice is metabolized It is also found that the blood sugar content in avian beriberi is greatly increased This fact has a practical bearing on infant feeding, a certain amount of vitamin can take care of only a limited amount of carbohydrate, and when starch is increased in the diet, the amount of vitamin-containing foodstuffs must be increased in proportion A second fact has been established in connection with the metabolism in the deficiency diseases, which is that in the absence of vitamin we not only obtain a negative nitrogen balance, but the whole metabolism goes wrong, this is particularly noticed in the negative balance of inorganic constituents The addition of vitamin puts the whole metabolism again on a normal basis Vitamin, when properly prepared and added to a diet of polished rice, makes that diet complete I have shown that no animal has yet been found able to live more than a short time on a vitamin-free food

When I first expressed the opinion that pellagra was a deficiency disease, I encountered great opposition, but now the etiology of this disease as a deficiency disease seems to be established It seems possible that pellagra is nothing but a chronic scurvy, whereas what we formerly knew as scurvy is only an acute form of the same disease The vitamin theory as to the etiology of rickets is at present merely a working hypothesis, but the results of animal experiments suggest that we are dealing with a deficiency disease due to a deficiency of vitamins which are not essential to life, or a partial deficiency of the ordinary vitamin The opinion of certain workers that rickets is due to a lack of calcium is very largely due to a misinterpretation of their experiments McCollum, and Osborne and Mendel have tried to demonstrate that butter has a decided effect on the growth of rats, and have stated that butter fat does not contain nitrogen I have succeeded in demonstrating that rats can grow very well without butter when a sufficient amount of vitamin is added to the diet of the rats, and hence I am unable to confirm the results of McCollum When working with yeast it has been noticed that rats fed on dried yeast grew well, but showed slight symptoms of scurvy, which disappeared when autolyzed yeast was used This possibly shows that rats require for their well-being both the beriberi and the scurvy vitamins Successful growth was also obtained by using phosphotungstic precipitate decomposed from autolyzed yeast, while the filtrate had no action whatever The fraction used was entirely free from material which could be extracted with lipoidal solvents, and this alone proved that the water-soluble portion of yeast is the only one responsible for the growth of the rats, in direct contradistinction to the statements of McCollum Experiments conducted in association with Dr Morris Stark show that McCollum's statement that casein loses, when heated with alcohol, its nutritive value is baseless We have shown, however, that by means of a suitable diet we can make rats grow twice as fast as on a diet regarded heretofore as normal, at the same time we have been able to stunt animals on a diet which might be designated as normal This result has been obtained in chickens fed on unpolished rice and still better by feeding unpolished rice and cod liver oil The same may be accomplished in rats on a diet of oats While cancer has nothing in common with the deficiency diseases we have shown that tumors in rats and chickens do not grow so extensively on a stunting diet as on a rich diet This makes it seem extremely probable that cancer is not of infectious origin but is due to a chemical cause

Group Similarities of the Deficiency Diseases
A Study of Infantile Scurvy

DR ALFRED F HESS There has been a difference of opinion as to whether or not the use of pasteurized milk can induce scurvy in infants The commission on milk standards, in its report of 1912, states that pasteurization of milk does not destroy its chemical constituents Determined to test the validity of this statement, we took a certain number of inmates of an infants' home, where all babies were fed on Grade A pasteurized milk which had been heated to 145 F for thirty minutes, and discontinued the use of orange juice No other change in the diet of the infants was instituted Almost all the infants who did not receive the orange juice developed a more or less marked form of scurvy, whereas those who continued to receive the orange juice were entirely free from this disorder The results of this investigation were questioned by some who were loath to believe that pasteurized milk could in any way lead to scurvy, and hence we extended the observation during the subsequent year The results were the same, so that I feel safe in saying that a diet of pasteurized milk leads to the production of scurvy in infants unless some antiscorbutic food is also given This scurvy is not, as a rule, of the florid type found in infants fed for months on a proprietary food, but may be described as latent or rudimentary scurvy It seems probable that this insidious type of the disorder is far more common than is generally recognized by physicians Raw milk is by no means comparable to orange juice as an antiscorbutic It is not to be inferred from these conclusions that the use of pasteurized milk is fraught with danger, but merely that it is an incomplete diet for babies and must be supplemented by an antiscorbutic food Secondary food factors seem also to play a part, malt preparations seemingly predispose to scurvy, and it seems probable that there is an intimate relation between the development of scurvy and the amount of carbohydrate in the dietary In considering the clinical relationship between beriberi and infantile scurvy the current clinical view which regards infantile scurvy almost as one of the hemorrhagic diseases and the current pathologic view which centers its attention on the changes in bone structure are far too limited in their scope Signs of the involvement of the nervous system are the characteristic manifestation of beriberi and infantile scurvy is not entirely free from nervous signs The knee jerks are frequently found exaggerated, and in some instances there is involvement of the optic disks and sensitiveness of the cutaneous nerves These symptoms disappear when the nutrition again becomes normal Dilatation of the right heart has been described in beriberi and a like condition has been demonstrated in infantile scurvy Edema is also a common symptom of the two conditions There is evidence demonstrating essential differences in the vitamins controlling the development of these allied disorders Observations have also been carried out as to the effect of infantile scurvy on growth It was found that although infants continued to gain for a few weeks following the discontinuance of orange juice they soon reached a stationary plane and for months were unable to rise above this level but increased in weight promptly when the antiscorbutic food was again added to their diet It is very probable that infants cease to gain during the third quarter of their first year of life for the want of this essential addition to their food, and fail to progress until mixed feeding is begun some months later The infant is protected during the first few months of life by the store of antiscorbutic material which it has inherited from its mother, and there is a constant negative balance of these essential substances dating from the earliest beginning of artificial feeding There is no reason why an infant should not receive orange juice when it is a month old Observations were also made on the growth in length as a result of which it was found that scurvy has a direct effect on such growth There was an exception to this, however, which shows that lack of growth does not play an essential part in the constitution of this disorder

DISCUSSION

Dr John R Murlin I have had the opportunity of observing pellagra in the U S hospital for the study of pellagra at Spartanburg S C So far it has not been proved that pellagra is a result of vitamin deficiency, neither has it been proved that vitamins are essential to life Dr Funk has shown the specific effect which can be obtained from extract of yeast and that added to the diet of polished rice it will cure polyneuritis in fowls, but it is a far cry from polyneuritis in fowls to pellagra In pellagra there is a perfectly symmetrical distribution of the lesions on the skin which must be attributed to the effects on the central nervous system, but the gastro-intestinal symptoms are equally as prominent Goldberger has shown that when normal persons are placed on a restricted diet such as is habitual among the poor of the South, they develop symptoms of pellagra and when an abundance of animal proteins are added to their diet, the pellagra can be cured To prove that the absence of vitamins produces the disease, it will have to be shown that food lacks vitamins and that the proteins which prevent the disease contain vitamins In pellagra the diet and the climate conduce to a peculiar gastro-intestinal condition The flora of the intestines is peculiar and may give rise to acid bodies which may be toxic, but there is no justification for the belief that the lack of vitamins is the sole cause of pellagra

Dr P A. Levene From the academic standpoint, the process of nutrition consists of two phases One is concerned with the production of energy required for the normal course of the functions of the organism, the other with the growth and repair of the tissue elements The first is a process of degradation, the second of synthesis There are many substances which can be converted into tissue elements by plants or bacteria, but which cannot be made use of for the same end by man A most perfect food is one which furnishes all the energy requirement with the least tax on the integrity of the tissues, and which at the same time contains in ready form all the elements required by the organism for the normal repair of its tissue elements In the light of these requirements a diet composed of homologous tissues approaches nearest the ideal On the other hand, a diet composed of an unusually large quantity of a single foodstuff is most taxing to the activities of the tissues It not only lacks some of the elements necessary to tissue repair, but also lowers the efficiency of the supply of these substances deposited in the tissues Such is the case in experimental polyneuritis Fasting is much less harmful than a diet consisting of polished rice alone A large intake of rice is more effective than a small one in producing beriberi Beriberi once produced may be cured by a well balanced diet, it may also be cured temporarily or partially by a minute quantity of certain tissue extract It is one of Dr Funk s merits to have introduced the name 'vitamin" for these substances The clinician for the present has to deal cautiously with the problem of vitamins Wherever possible he will have to avoid the one-sided monotonous diet

Dr L Emmett Holt Scurvy has been much more frequently seen since the general introduction in this city of pasteurized milk To my mind the evidence is conclusive that the connection is one of cause and effect Boards of health have been properly impressed with the part that milk has played in the transmission of septic sore throat and typhoid fever, but it is unfortunate that they should have neglected to warn the public that pasteurized milk may produce scurvy It has been asserted that if scurvy occurs in an infant it is always the fault of the milk formula and cannot be ascribed to the heating This is a difficult position to maintain While it is certainly true that the occurrence of scurvy shows that the food is not proper, this is far from proving that other proportions of the fat, protein and carbohydrate used would have given a different result The addition of cereals to milk as commonly employed in infant feeding does not seem to give any protection against scurvy if the milk is heated, but rather that additions of considerable amounts of carbohydrates, particularly in the form of starchy foods and maltose mixtures increase the liability to scurvy in heated milk I have now under observation an infant who has developed scurvy on a diet of heated milk and high carbohydrate in spite of the fact that 1 ounce of orange juice had been given daily for a month before the first symptoms were seen There is certainly an individual predisposition to scurvy which is of some importance Only a small proportion of the children fed on pasteurized milk develop the condition but the point to be emphasized is that it occurs in some infants even though fruit juice is given in the usual amounts and that this is more likely to occur if the carbohydrates in the food are high I do not wish to be understood as voicing an indictment of pasteurized milk, but simply to call attention to the disadvantages which must be considered as well

Dr Warren Coleman One of the most interesting phases of the vitamin problem for clinicians is the question whether the diets used in the treatment of any of the commoner diseases are deficient in these important substances There is no common disease of adults in this latitude which is recognized to be due to the lack of vitamins Yet, it is not impossible that ill defined types of disorders now thought to be due to disturbance of function, or some of the symptoms of well established diseases may have this origin I am more ready to credit this possibility because of my experience with typhoid fever I believe the very course of the disease has been altered by giving patients all the food they require instead of only a part of it I no longer consider diarrhea a symptom of typhoid fever, except, perhaps, in the prodromal stage, but think it is the result of improper diet, and it ceases when the diet is arranged properly Delirium and the typhoid state are not essential symptoms of the disease When delirium occurs it is due to the fact that either the temperature is elevated above a certain height for a particular individual, or to the elevated temperature plus starvation If in so well known a disease as typhoid fever such prominent symptoms could have been considered essential symptoms of the disease it is quite possible that some of the symptoms of other diseases, or at least some disorders not now understood may be found to be due to diets deficient in vitamins It may be well however, to direct attention to the fact that the so-called bland diets of the textbooks ordinarily consist of foods with a high vitamin content, unless they have been heated too long

Dr Morris Stark There is enough evidence in the literature to tempt one to assume that rickets is a metabolic deficiency If experiments now being conducted can definitely show, and I have no doubt they will, a change in the mineral metabolism as a result of the administration of vitamin substances in themselves free from these salts in any appreciable amounts, in addition to the diet which produced the deficiency disease, the point is proved and the mystery surrounding rickets solved Experiments have shown that boiling casein does not destroy its food value, but it does destroy the vitamins From many authoritative sources we are led to believe that yeast contains a large proportion of vitamin The effect of the administration of autolyzed yeast to rachitic children is a distinct increase of appetite

Dr Abraham Jacobi Scurvy is frequent nowadays when so many babies are artificially fed Pasteurized milk with a cereal will sometimes prevent or cure scurvy, but not every overrefined cereal will do this, only cereal in the raw state If there is no husk left on it there is no advantage to the baby Raw oatmeal or barley are the most efficacious materials to add to the milk Breast-fed infants rarely have scurvy, probably because the milk from day to day and from morning to night is never the same, it has the advantage of being changed frequently

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below

American Journal of Insanity, Baltimore

April LXXII No 4 pp 591 715

1 Pathologic Findings in Sympathetic Nervous System in Psychoses A Myerson, Boston
2 *Wassermann Test in Practical Psychiatry L G Lowrey, Hathorne Mass*
3 *Sensibility of Nipple Area with Reference to Mental Disease M E Scheetz, Washington, D C
4 *Treatment of Paresis B D Evans and F H Thorne, Morris Plains, N J
5 *Intracranial Injection of Salvarsanized Serum D M Wardner, Cedar Grove, N J
6 Study of Aphasia Apropos of Case of Verbal Amnesia and Alexia A Gordon, Philadelphia
7 Unique Murder Case with Application of New Law Governing Expert Testimony J W Putnam, Buffalo

2 **Wassermann Test in Practical Psychiatry**—Statistics are presented by Lowrey dealing with the results of the Wassermann test on the blood serum of 1,600 cases admitted to Danvers State Hospital Of 864 male cases tested, 164, or 19 per cent, were positive Of 736 female cases, 92, or 12 5 per cent gave positive tests Of the 1,600 cases tested, 256, or 16 per cent, were positive Doubtful tests occurred in 3 87 per cent of the cases Including cases with positive spinal fluid test and negative or doubtful blood test, 273, or 17 per cent of 1,600 admissions, give a positive test at some point Of 164 positive blood tests among males, 113, or 68 8 per cent, occurred in cases of nervous syphilis Of 92 females with positive blood test, 32, or 34 8 per cent, were paretics Of 256 cases with positive blood test, 145, or 56 7 per cent, are cases of nervous syphilis Excluding paretics from all figures, positive tests occurred in 7 6 per cent of 1,455 admissions Of the nonparetic cases with positive blood, 20 are "organic," 80 are "functional" and 10 are "unclassed" It appears that, if an insane man has a positive blood test, the chances are better than even that he will be a paretic, while if a positive test appears in an insane female, the chances are that she will not be a paretic When paresis is excluded, the chances are about three in four that the person with positive blood will have a "functional" psychosis Among the paretics of this series, the blood test was positive in 87 5 per cent and negative in 10 3 per cent The spinal fluid test was positive in 87 2 per cent and negative in 8 5 per cent, while the test was positive in both fluids in 75 per cent of the cases Of 276 cases with test on the spinal fluid, there are 126 positive results Of these, 109 had blood and fluid test both positive, five had doubtful blood and positive fluid test, 12 had negative blood and positive fluid test Of the 126 cases with positive fluid test, 121 were paretics, two imbeciles, one was organic dementia, one a heroin case, one psychoneurotic The latter five may in the course of time develop paresis

3 **Sensibility of Nipple Area**—The ten cases examined by Scheetz show the following A decrease or lack of sensitivity to light touch throughout the whole areola nipple region. The retention but inaccurate localization of pressure sensation under normal conditions The exaggeration of pain sensations, both in the erected and in the unerected states, but more intense in the former The increase in sensitivity for pressure and pain stimuli when an erection of the nipples was induced The "reference of the sensations to the true sexual organs, at times by the stimulation of the unerected nipple, but in nearly every case when the erected nipple is stimulated That diseases of the sexual organs tend to influence mental life has long been recognized, but little is known scientifically regarding the normal sexual feelings and sensations This report aims to give for one of the accessory sexual organs a beginning of this information, without which there will persist a sharp clinical distinction between mental and physical, which does not in reality exist

4 **Treatment of Paresis**—In the New Jersey State Hospital at Morris Plains, Evans and Thorne have treated fifteen patients suffering from paresis with salvarsan and neosalvarsan Fourteen of these patients were treated by the intraspinous method of Swift and Ellis and one by the intraspinous and intracranial methods combined With the latter method two intracranial treatments were given at four weeks interval along with three intraspinous treatments The largest number of intraspinous treatments given to one individual was ten and the smallest number three Three of these patients showed mental and physical improvement, five showed physical improvement only, two died during the course of treatment, two died ten and thirteen months, respectively, after treatments were discontinued, the remainder showed no improvement whatever Of the three who showed mental and physical improvement one was discharged and still remains in good physical and mental condition, having returned to work One showed the first signs of improvement three months after receiving last treatment The third died with convulsions ten months after treatment The number of treatments given to each patient was insufficient to reduce the intensity of the Wassermann reaction either with the blood or the cerebrospinal fluid The improvements observed following the treatments may be seen among the same number of paretics who have received no special treatment The authors believe that the amount of salvarsan which can be introduced safely into the central nervous system is too small, and the intervals are too long between the treatments, to be of great value in moderately advanced cases The intracranial method seems unnecessary The same results can be obtained with the intraspinous method

5 ***Intracranial* Injection of Salvarsanized Serum**—Of fourteen patients treated by Wardner five improved sufficiently to be able to go back to their work and to date have remained well for from seven to eleven months At the end of eleven months, one of these patients had a bad relapse He was immediately brought back to the hospital and he responded immediately to additional applications of the serum At present he is well, mentally and physically, and has parole of the grounds Three other well developed patients have improved sufficiently to be put on parole of the grounds and are doing efficient work about the hospital Three others have shown fairly marked physical and mental improvement but cannot as yet be trusted at large Two have died In both of these patients, necropsies were performed and both showed, grossly and microscopically, changes suggestive of general paresis The immediate cause of death was in one case bronchopneumonia and in the other, who had right-sided convulsions at intervals, there was found a large cyst underlying the left motor cortex This last case had previously shown a well marked improvement and at the time of death was on parole Two cases have shown no improvement Both mental and physical improvement has generally been observed after the second or third operation, and has followed

so closely on the treatment as to practically preclude the idea of coincidence The maximum amount of improvement has occurred as a rule after six or seven treatments

8 Advantage of State Hospital for Indigent Crippled and Deformed Children in Advancement of Orthopedic Surgery in State A J Gillette St Paul
9 Loose Bodies in Knee Joint Report of Cases M S Henderson Rochester Minn
10 Effects of Motion and Rest in Surgical Diseases J P David Paris
11 *Results of Fracture of Os Calcis Report of Cases F J Cotton and F F Henderson Boston
12 Fracture of Tuberosities of Tibia Report of Three Cases J W Sever Boston

9 **Loose Bodies in Knee Joint**—Cases are reported by Henderson to illustrate the various types of loose bodies to be found in joints He says that loose bodies may have as their primary cause some condition such as osteo arthritis or Charcot s disease, but the secondary cause is direct or indirect trauma Osteochondritis dissecans is a group standing more or less distinctly out from the rest The bodies seem to be produced by very slight indirect trauma It is however, difficult to estimate the degree of indirect trauma and for that reason they had better be considered as due to trauma rather than to an actual disease Trauma direct or indirect is essential to the production of a loose body Henderson is convinced that surgery offers the only permanent relief and the general condition of the patient being satisfactory, the bodies should be removed

11 **Fracture of Os Calcis**—Os calcis fracture of the usual compression type, Cotton and Henderson regard as being one of the most serious lesions met with, so far as future function is concerned It is of as serious prognosis (not as to life, but as to use) as fracture of the femur at the hip Ordinarily speaking the man who breaks his heel bone is 'done ' so far as his industrial future is concerned Late operations for correction are useful but far from ideal in results palliatives (plates, pads braces and shoe modifications) are usually useless Out of one series of sixteen cases cited only eight got even a useful result and in one of these the displacement was so slight that one of the authors felt that no reduction was called for Of the other seven, four recovered in spite of conservative' treatment but of these four, three still had trouble The other three were cases that had been properly reduced and in all three the result seems excellent In four which had been manipulated only, the result was poor, and of these eight practically untreated only four got any kind of result In a second series of twelve cases none had been treated and there were no decent results at all Out of the twelve, nine are definitely permanent cripples Two are due to improve and may possibly work again—one probably will get back to work.

Boston Medical and Surgical Journal

May 4 CLXXIV No 18 pp 633-666

17 *Use of Duodenal Tube for Diagnosis and Treatment. (To be continued) F W White Boston
18 Hallux Valgus C F Painter Boston
19 Choice of Climate in Cases of Bright s Disease and Nephritis G Hinsdale Hot Springs Va
20 *Pituitary Body and Renal Function K Motzfeldt Christiania Norway
21 *Simple After Treatment for Perineal Wounds E B Young
22 Exostosis of Upper Angle of Scapula L T Brown Boston Boston

17 **Use of Duodenal Tube for Diagnosis and Treatment**—White regards the duodenal tube as being a real contribution to medicine, although the field for its use, both in diagnosis and treatment, is somewhat limited He used the tube in 90 cases, fifty-six for diagnosis, in thirty-four for treatment The tube reached the duodenum in about 30 per cent of the cases within fifteen minutes, in about 30 per cent more within a half hour and in about 20 per cent more of the cases within one to six hours In about 20 per cent of the patients the tube had to be left in over night in order to reach the duodenum Some difficulties were met in adapting the routine to different sizes of patients and different sizes and shapes of stomachs The quickest way to enter the duodenum White found is to get the tube close to the pylorus within a short time This is best accomplished by using a light tube with a heavy tip swallowed by the fasting patient in the erect position feeding the tube in slowly and steadily

20 **Pituitary Body and Renal Function**—In one case of diabetes insipidus studied by Motzfeldt feeding the patient with the posterior lobe of the pituitary body checked the diuresis while administration of the anterior lobe had no such effect In a second case four posterior lobes of the pituitary body taken in the evening proved to be sufficient to diminish the output of urine to such an extent that she could sleep comfortably every night In a third case the diuresis went down from 6 000 to 1,500 c c, and the specific gravity increased from 1,003 to 1,007 on subcutaneous administration of pituitary extract (1 c.c by 3)

21 **After-Treatment for Perineal Wounds**—It is Young's aim to maintain the greatest possible degree of cleanliness and dryness as under such conditions infection and irritation are least likely to occur After twenty-four hours, when the bleeding has ceased the gauze perineal pad is omitted and the genitals and fissure between the buttocks kept liberally covered with a drying and antiseptic powder, the best being the compound stearate of zinc with boric acid The powder is best applied with the patient lying on the side, the upper buttock being raised and the powder thrown into every fold It is not sufficient to dust lightly or use a powder blower The parts must be covered thickly, especially between the buttocks and kept so throughout the healing if the best results are to be obtained Although the powder gradually becomes moist it gives excellent protection to the skin, is mildly antiseptic, and sheds water to an amazing degree With reasonable care it is usually possible to maintain absolute dryness If there is considerable tendency to moisture and maceration of the skin the application of a 10 per cent aqueous solution of ichthyol before dusting with the powder will be found effective The patient, free from any dressing lies on a small pad which collects any discharge from the vagina or elsewhere, and can be changed whenever necessary The genitals are carefully washed after urination and defecation and as often as may otherwise seem necessary

144 **Chronic Arthritis**—On the basis that chronic arthritis may be of infectious origin, McCrae, says, one should give up the habit of calling such conditions "rheumatism" This only means a hazy conception in the minds of most of us and we need clear ideas and definite conceptions in dealing with chronic arthritis, which has nothing to do with rheumatic fever, a definite infectious disease readily recognized in the majority of cases If there is doubt in the diagnosis of an acute arthritis, as there may be for some days, it is wiser to feel that other forms of arthritis have to be excluded and it is better to make the diagnosis of rheumatic fever last rather than first The occurrence of permanent changes in or about a joint, even though very slight, speaks against rheumatic fever The finding of the original focus of infection is more essential It is not well to think that this is an easy matter, sometimes it is, but more often the search is difficult In general, the measures to be adopted are (1) early recognition before material damage is done so that the proper measures can be adopted at the onset, (2) thorough search for the focus of infection and efficient treatment of this if found, (3) every effort to improve the patient's powers of resistance, and this is particularly important if the source of infection cannot be found, in the hope that the patient may overcome the infection by his own powers of resistance This involves the best possible nutrition, good hygiene, free elimination and the blood in good condition, (4) the effort to lessen the damage to the joints, under which head come the proper uses of exercise and rest, local measures, such as aid the circulation or relieve pain, (5) the relief of pain both for the sake of the patient and to allow of movements in some cases, (6) the prevention of deformities

146 **Gonococcic Purulent Conjunctivitis Treated by Iced Normal Salt Solution**—The temperature which can be maintained with cold is almost 0 C, under which the gonococci are killed instantly On this assumption and the assumption that gonococci are found only in superficial epithelial tissues and do not penetrate deeply, Heckel says, that we have in iced normal salt solution a harmless effective germicide, easily produced, maintained and easily applied He cites two cases in which its use was followed by excellent results

6 *Nature and Treatment of Concussion T E Harwood
7 Three Cases of Paroxysmal Hemoglobinuria in Soldiers D MacManus
8 Case of Heart Block in Jaundice R D Rudolf

6 **Nature and Treatment of Concussion**—Harwood believes that there is some relationship between errors of refraction and concussion in its expression of a neurasthenia A patient suffering from head injury or shell shock is usually put to bed and rested in every possible way, almost the only organs of his body on which any constant voluntary effort falls are his eyes In fact, throughout his convalescence his chief energies are, consciously or unconsciously, being spent on his eyes, because without the use of his eyes he can do little or nothing, and during all his waking moments a large proportion of his diminished available energy is being spent on them, the result being that the rest of his body is starved Various functional effects follow, and the patient falls a ready victim to organisms normal to the body and their toxins But by correcting the refractive error the work which the eyes have to do can be reduced to a minimum

11 *Nonprotein Nitrogen of Blood, Especially in Its Relation to Nephritis and Renal Function F D Boyd
12 Case of Enteric Intussusception J Fraser
13 Cases of Perforating Pyloric and Duodenal Ulcers W A Mackay and I Macdonald
14 Flash Boiler as Field Equipment W Robertson
15 Royal College of Surgeons of Edinburgh C H Creswell

11 **Nonprotein Nitrogen of Blood**—Boyd is convinced that nitrogen retention does not occur in all nephritics He says that when the nonprotein nitrogen of the blood rises to 50 mg per cent it is a distinct warning of grave renal inadequacy, and is an urgent call for a rigid nonnitrogenous regimen Nitrogen values round about or over 100 mg per cent justify the gravest prognosis, but there is no definite relationship between nitrogenous retention and high blood pressure The estimation of nonprotein nitrogen of the blood is of great clinical value as a guide to prognosis and to treatment in all cases of nephritis The treatment of nitrogen retention must be principally dietetic When a nephritic with nitrogen retention comes under observation it is well, if strength permits to withdraw all nourishment, satisfy thirst with distilled water, and administer purgatives Considerable nitrogenous waste can be withdrawn by the bowel Hot-air baths or hot packs are of value After a period of twenty-four hours' rest nonprotein diet is commenced consisting of water arrowroot, cream sugar and such stewed fruits as are poor in benzoic acid, namely, apples, prunes and figs This diet can be kept up for a week or even two weeks without the patient suffering It supplies sufficient energy for the bodily requirements, and if nitrogen retention is not excessive may cause a definite fall in blood nitrogen At the end of the period milk may be added and more inspiring farinaceous foods than water arrowroot In the early stages of an acute nephritis, even when there is no nitrogen retention such a diet is always desirable, for even though the kidney may be able to excrete waste nitrogenous bodies in doing so it is working, not resting and work is not good for an organ in an active state of inflammation In chronic nephritis dietetic treatment must largely be governed by an estimation of blood nitrogen If there be no nitrogen retention it is inadvisable to keep the patient on a strict nonprotein diet, as nutrition suffers Short periods of nitrogen-free diet are often useful and beneficial to the renal function and the cardiovascular symptoms, but the patient s nutrition must always be kept in view

16 *Vaccine Treatment in Streptococcal Puerperal Fever A J Chalmers and O Farrell
17 Blastomycosis (?) in Central Africa A. Y Massey

16 **Vaccine Treatment in Streptococcal Puerperal Fever**—Chalmers and O Farrell cite two cases of puerperal fever caused by the fecalis group of streptococci in which vaccine therapy was successful The first patient, a multipara, had an easy confinement which was conducted without intravaginal examination. She kept quite well for seven days when for the first time she received an intravaginal douche after which the fever began No organisms were obtained from the peripheral blood but an intra-uterine swab produced a pure growth of a streptococcus which eventually proved to be *Streptococcus versatilis* belonging to the fecalis group She at first only received antistreptococcal serum, but on admission into the hospital the uterus was thoroughly cleansed An autogenous vaccine was given in a 5 million dose six days after the preliminary dose of *Streptococcus salivarius* (stock vaccine) This vaccine also appeared to do no good and five days later the patient became obviously worse, when 200 millions of the fecalis group vaccine was administered She made a good and rapid recovery This is obviously a chronic case in which the treatment of uterine cleansing and antistreptococcal serum did much good, while the heterologous vaccine did no good, but a large dose of the homologous vaccine produced a cure

The second case was a very severe type of fever which had lasted six days, and when first seen had a temperature of 104 6 F There was much purulent discharge from the uterus The uterus was douched out with antiseptics but this had to be stopped on the third day as the patient s friends refused to allow it to be done and she had to trust entirely to vaccine therapy As some human fecal matter had been observed in the vagina it was decided to treat her at once with the same vaccine as that made from the first case, and this was done in less than twenty-four hours after the case had been first seen She received a 5 million dose, and, as the effect was to slightly lower the temperature, and as the patient showed some improvement, three days later she received 50 millions, when the temperature gradually fell reaching 100 F on the sixth day after the first vaccine dose On the next day it rose to 102 6 F in the evening, and next day (eighth day after first injection), she received 200 millions the temperature declined and reached normal on the third day after this dose, and the eleventh after the commencement of vaccine therapy, she made a good recovery

24 *Precipitin Reaction in Tuberculous Fluids S R Gloyne
25 Imperforate Hymen in Baby H R Spencer
26 Case of Imperforate Hymen W Robertson

19 **Auscultation and Gunshot Wounds**—Well recognized and charactertistic as are the murmurs produced by the existence of traumatic openings in the walls of the blood vessels, Makins is of the opinion that the routine employment of the stethoscope for their detection seems hardly so generally adopted as should be the case The importance of this method of examination is obvious in any class of wound but it is especially valuable in the case of the multiple wounds inflicted by the various forms of fragments derived from the bursting of high explosive shells and bombs Three cases are cited to emphasize the value of this method of physical examination and to impress the fact that in any case of swelling of a limb in connection with a gunshot wound the stethoscope affords a ready and certain means of establishing a diagnosis Further, observation of the point at which the bruit is loudest and highest pitched will serve to localize the exact position of the lesion Makins points out that the method is far more reliable than the uncertain practice of examining for the state of the distal pulse, for this is obliterated only if the vessel has been completely severed, or in the rarer instances in which large masses of hard clot exist to compress it, while diminution of size and force is more likely to be due to moderate pressure from without than to the existence of a lateral wound in the wall of the artery

24 **Precipitin Reaction in Tuberculous Fluids**—Four definitely tuberculous fluids were tested (three contained bacilli and the fourth, though no bacilli were found, was verified postmortem) by Gloyne. Of these four fluids three gave positive reactions (75 per cent) Fourteen fluids were also tested in which the diagnosis could not be definitely proved by the finding of bacilli, but in which a lymphocyte count, high protein content etc, strongly suggested a tuberculous origin Of these, five (36 per cent) gave a positive reaction two (14 per cent) a doubtful and seven (50 per cent) a negative result. Four nontuberculous fluids used as controls were all negative Gloyne is of the opinion that the test may be of some use in cases of tuberculous effusion in which bacilli have not been found in the fluid

42 Surgical Treatment of Pseudarthrosis After Fracture of Lower Jaw (Traitement chirurgical des pseudarthroses dans les fractures du maxillaire inferieur) Cavalie

37 **The Giant Magnet as Aid in Extracting Scraps of Metal from the Brain**—Rocher shows by illustrations how the magnet causes waves in the brain tissue which help to mobilize the bullet or scrap of shell The attraction should always be applied so as to draw the bullet out by the path it entered He has made a special study of the subject on cadavers, and points out the dangers to be avoided When the foreign body is in quite deep, he interposes a narrow steel funnel, 5 cm long, fitting over the tip of the magnet It is important to draw the bullet out by its tip, and under control with the Roentgen rays it is possible to guide and draw the tip around to the best position for its extraction from the tissues

39 **Prophylaxis of Scarlet Fever, Diphtheria, etc, in Hospital**—Lemoine and Devin relate that last January a large number of cases of scarlet fever, diphtheria, measles and mumps were brought to the improvised hospital in their charge, and there was only one large hall where the men could be placed They had a few low partitions put up to mark off the sick with the different diseases, but isolation was out of the question The sole reliance was on the Milne method of prophylaxis, veiling head and chest with a gauze curtain which was sprayed with tincture of eucalyptus and an antiseptic three times a day Every three hours the throat and nasopharynx were painted with iodized glycerin and an antiseptic oil was instilled into the nasal passages These measures were done by the physician himself or by a nurse tending exclusively one group of patients When the man was allowed to get up, he had to stay in part of the room given up to suspects, and three times a day, the throat, nasopharynx and the nose were disinfected During the month this treatment was applied to 10 men with measles, 18 with scarlet fever, 16 with mumps, and 12 with diphtheria, and no case of contagion and no complications developed The method must be applied painstakingly by one who believes in it and it takes patience and perseverance When this can be realized, the period of isolation after infectious disease can be materially shortened

54 *Differential Diagnosis of Syphilis of the Mouth (Syphilis de la bouche Gommes perforantes du voile du palais) Gaucher

50 **Tests to Control the Hearing**—Gosset mentions a number of means with which simulation or exaggeration of deafness is readily detected during lip reading exercises

52 **Sodium Perborate in Treatment of Wounds**—Bourgeois applies the sodium perborate as a dry powder As it becomes moistened by the secretions it generates oxygen and acts like the ordinary solution of hydrogen dioxid, only that it is alkaline He fills up the wound cavity with the powder, without draining, with a flat dressing above, renewed every day at first

53 **Operative Treatment of Hydrocele by the Inguinal Route**—Tourneux comments on the disadvantages and complications liable to follow an operation on the scrotum to cure hydrocele, especially the difficulty of ensuring and maintaining asepsis in this region There is often a tendency to inguinal hernia, also, in men with hydrocele, especially the congenital There are thus a number of advantages in operating on the hydrocele through an inguinal incision, as Gomoiu and Phocas have been doing with great success They had published by 1914 sixty-eight cases with unfailingly excellent results It is very easy to draw up the testicle through an incision in the inguinal or inguinal-pubic region, an assistant pushing it up from below The tunica vaginalis soon presents in the incision and is seized with two forceps and evacuated Then the testicle is drawn out and the serosa is turned as by the usual technic, resecting it or not as indicated Phocas punctures and evacuates the hydrocele as the first step, but Tourneux does not think this is necessary but rather a drawback as it is easier to find and hold the vaginalis when it is distended He has been much impressed with the ease, simplicity and ideal results of this method of treating hydrocele It takes only a few minutes and the incision heals promptly as held together with clips The reaction inside the scrotum is much less than with the scrotum incision, the patient is kept in bed but a few days—Phocas says only two or three—and he can leave the room in seven or eight Tourneux thinks that this principle of access through the inguinal region could be applied to a number of other affections of the testicle and cord

54 **Syphilis of the Mouth**—Gaucher expatiates on the necessity for bearing the possibility of syphilis in mind whenever a sore throat shows a median predominance of the lesions, or when a syphilitic complains of sore throat Ordinary sore throat usually concentrates on the tonsils and their vicinity When the finger feels a deep hardness in the velum you are justified in asking as you palpate the palate "When did you get your syphilis?" Tuberculous ulceration of the velum is rare and is more painful than the syphilitic, and is surrounded by yellow points, the miliary tubercles Syphilitic lesions of the tonsils are rare, but there is a febrile type, a type that resembles epithelioma, and a gangrenous type usually from secondary infection The limitation to one side and the absence of glandular involvement help in differentiation Gaucher adds that as potassium iodid is said to promote epithelioma, it is better not to give it in dubious cases, mercury is always available A solitary gumma in the pharynx is liable to be mistaken for an ordinary tumor Diffuse syphilitic lesions of the palate and pharynx have such an insidious onset that irreparable damage may have been done before their presence is suspected Any change to a more nasal tone to the voice is suspicious, and redness or other sign of anything wrong in the mouth or throat of a syphilitic calls at once for careful palpation throughout

58 *Anemia and Enlargement of the Spleen in Girl of Nine (Hochgradige Anamie mit Milztumor—Pseudo Banti—beim alteren Kinde als Folgeerscheinung septischer Infektion in den ersten Lebenswochen) H Kleinschmidt
59 *Is There an Initial Fever in Tuberculosis? (Zur Frage des Tuberkulose Initialfiebers) H Kleinschmidt

55 **Measles Problems** —Wagener studied some epidemics of measles in five different towns during 1913 but was unable to find anything to confirm the assumption that measles can be transmitted by inanimate objects or by healthy persons A schoolroom of children becomes infected by one or more of the children having been exposed outside the school Each infects those in its immediate vicinity alone, and these in turn others until all in the room have been infected by the end of three weeks This phase is followed by the period in which the children at home too young to go to school, and the adults become infected This sequence of events can be clearly traced in places with a one room schoolhouse An epidemic develops only after an interval of at least three years since the last general epidemic of measles Those who escape a general epidemic are the children under 5 months old at the time All who escape are thus below the school age, as all the schoolchildren who have not already had measles contract it without exception during a village epidemic The epidemic reaches its height in twenty-five or six days and then declines the younger children and adults infection representing the declining period Among the 694 cases of measles in the five different localities, complications were observed in 27 26 per cent including 77 cases of otitis media, 54 of conjunctivitis, bronchitis in 18 and pneumonia in 9 while 27 children were left with chronic enlargement of lymph glands, 15 with severe anemia and 12 with chronic disease of the middle ear He found no instance of primary immunity The exanthem showed invariably in the throat when the children were examined during the days just preceding the skin eruption, in one case it appeared before Koplik s spots

He found no instance in which a child escaped the disease when exposed for the first time after the age of 5 months None under 4 months old developed measles and only one infant of five months although all were in constant contact with brothers or sisters with the disease He thinks it is possible that young infants escape because they breathe only through the nose and thus the measles germs do not have free access to the throat If an infant s nose is stopped up this protection is lost, the infant is as liable then to contract measles as older children Wagener is convinced that transmission by fomites is practically impossible and he has long omitted precautions in this line and has never had a case of transmission traceable to this omission He calls attention further to the fact that over 49 per cent of persons who had already had typical measles in former epidemics, developed symptoms on the part of the upper air passages digestive tract sore throat or conjunctivitis, while other members of the family were having measles These disturbances were observed exclusively in 183 families where there were cases of measles, and they never reached a degree beyond that observed with such phenomena as complications or part of measles They coincided further, with the measles in the family There is little doubt that the disturbances were the work of the measles germ, and hence that the individuals were carriers—for the time being—and liable to spread the disease There is much evidence to prove that these carriers are responsible for the instances of transmission of the disease which have been attributed hitherto to transmission by fomites or healthy third parties

56 **Importance of Extractives in Infant Feeding** —Heim relates that twenty-five guinea-pigs fed exclusively on cow s milk all died in from four to fifteen days, others died promptly likewise when cellulose was added to the milk, but the animals developed normally when malt extract was added to the milk-cellulose mixture He prepared an alcoholic extract of the germinating barley, and this seemed to contain some substance able to compensate for the deleterious action of the cow's milk Seven infants not thriving on cow s milk seemed to benefit likewise from this extract of germinating barley, his results confirming those of Aron and emphasizing that we must pay more heed to the extractives henceforth in artificial feeding of infants

57 **Intussusception of the Intestines in Children** —Nagel reports three cases in infants six or seven months old, one his own child The invagination corrected itself spontaneously in one the nature of the disturbance not being recognized In the others it subsided in less than thirty hours under injections of water or oil, a pint and a half, from a height of 30 inches, with the pelvis raised The injection was repeated every two or three hours until the desired result was attained, five or six were generally enough The intussusception is reduced the more readily the nearer the anus Blowing air into the intestines with a T tube and bulb has also proved successful in some instances With much vomiting lavage of the stomach is useful To quiet the bowels after the injections, small doses of opium may be useful Hirschsprung recommends cautious massage This is scarcely feasible, however, unless the invaginated portion can be palpated Nagel strongly advocates examining the abdomen and rectum under general anesthesia This alone may break up the invagination

There is scarcely any other affection in infancy which strikes so like lightning from a clear sky Nagel's own healthy infant was nursing happily in perfect health when it suddenly screamed, became livid its limbs hanging loose, the breathing deep and slow the pulse imperceptible, the abdomen relaxed The child lay in complete apathy, its body cool This state lasted for three minutes and then a few slow movements of its limbs followed Then it screamed again and sank anew into the alarming apathy and atony, which lasted five minutes this time Then came a restless sleep during which it moaned and grimaced A third attack followed succeeded by a brief, leaden sleep The pallor was not so extreme by this time but the pulse was small and fast, the limbs relaxed and no attempt to move them was made Palpation of the soft abdomen seemed to hurt the child a little but no special tender point could be found While being examined it vomited and then had another attack of pain after which it slept again As it slept it seemed to be regaining its normal aspect and when it woke, sat up and played as if nothing had happened It passed a few hours later a stool of almost exclusively fresh blood and mucus, and the stools showed mucus for several weeks but no blood The boy is now 4 years old, strong and well, and has never presented any such symptoms since In the second case, there were four or five of the attacks and one followed an enema of ¾ liter of tepid water, but then there were no more The first day there had been three stools of almost exclusively blood and mucus There was no fever in either case and no recurrence during the years since In the third case the attacks continued for a day and a half diminishing in intensity Enemas of a liter of tepid water seemed to relieve, but there is nothing to show that they corrected directly the invagination Hirschsprung s eleven cases all terminated fatally

58 **Intense Anemia with Enlarged Spleen in Girl of 9**—Kleinschmidt describes the puzzling syndrome and the numerous futile attempts to explain it before it was finally traced to the results of severe and protracted septic suppuration of the umbilical cord the inflammatory process evidently having involved the portal vein Türk has published two similar cases and Epstein one in which there had been multiple phlegmonous processes The syndrome is characterized by recurring hemorrhages in the gastro-intestinal tract entailing extreme anemia with exhaustion of the bone marrow and enlargement of the spleen The child has improved and is doing well on a diet rich in vegetables, for the iron in them and for correction of constipation, the tendency to hemorrhage is combated by continuous systematic administration of calcium chlorid

59 **Initial Fever with Tuberculosis**—Kleinschmidt thinks that the assumption of an initial fever in tuberculosis will have to be deferred until more data have been accumulated He reports the case of an infant nursed by the mother in the last stages of consumption After her death the child seemed to be thriving and its temperature was constantly normal until the fifty-first day when the Pirquet test elicited a positive reaction The temperature persisted normal for another two weeks, but then rose and other symptoms of generalized tuberculosis rapidly followed, fatal at the age of 3 months

88 *The War and Venereal Disease (Guerra e problema sessuale) F De Napoli

89 *Splenectomy in the Pathology of the Liver and Blood (Estirpazione della milza nella patologia del fegato e del sangue) L Silvestrini

82 **Grafts and Implants in Biology and Surgery**—Minervini has had considerable experience in this line and here reviews the results accomplished by himself and others He declares that as the capacity for growth of the tissues is greater the younger the tissues, there is every reason to assume that grafts from fetus and newly born cadavers offer the maximum prospects for success He has been thus using for ten years embryonal tissues for free grafting in his surgical work Skin from fetuses and still born infants proved exceptionally useful to cover the raw spaces after extensive burns The skin of fetuses of the seventh, eighth or ninth month was used fresh or after having been kept for a few hours or days Flaps transplanted from the back or chest of the fetus or new-born infant grow rapidly to the tissues and become solidly fastened in a few days His communication commending the use of embryonal tissues was published in 1911 and a later report was read at the last international medical congress

83 **Abderhalden Reaction in Tuberculosis**—Datta got positive results in the early stages of tuberculosis but not in the advanced cases The findings were positive also in some of the supposedly healthy persons tested and also in some patients with nontuberculous affections

88 **War and Venereal Disease**—De Napoli discusses the general measures for prophylaxis of venereal disease adopted in recent wars and in the present war He advocates in prophylaxis means to prevent clandestine prostitution, collecting the women in brothels kept under strict medical supervision, with medical inspection at regular and unexpected hours, each establishment to be equipped with a sanitary toilet room near the entrance where a trained attendant should inspect the man as he enters and apply measures to sterilize and protect, and again as he is ready to leave, in addition to the hot water and mercuric chlorid solutions for immediate cleansing which should be always in readiness for immediate use De Napoli relates that he knows of instances in which venereal disease was intentionally acquired to obtain sick leave In his service at Bologna he has been impressed not only with the frequency of venereal diseases, but with the predominance of the ulcerating forms

89 **Splenectomy in the Pathology of the Liver and Blood**—Silvestrini found that rabbits bore the removal of the spleen without disturbance, but they did not develop quite as well as the controls The liver showed no signs of anything wrong at first, except possibly a lesser production of bile But gradually hyperplasia of the lymphatics developed, first in the vicinity of the portal vessels and then inside the liver lobes This hyperplasia is evidently a compensating process in the lymphatic elements in the depths of the liver, it explains the increase in size of the liver which follows removal of the spleen There were also slight changes en-

dent at certain points in the liver, suggesting that the liver tissues had become less resistant to abnormal influences These changes occurred indiscriminately in the different lobes of the liver On the basis of these findings and those reported by others, Silvestrini advocates splenectomy in chronic hemolytic jaundice with enlargement of the spleen also in hemolytic anemia and in malaria with much enlarged spleen and rejects it in generalized leishmaniosis in infantile anemia with splenomegaly, hyperglobulia with splenomegaly, and in leukemia He presents the arguments for operation or abstention in these conditions emphasizing the class of cases in which this 'medical surgery' is especially indicated in the hope to act on the general disease by removing the spleen

92 **Syphilis of the Stomach**—Clark advocates a course of treatment as for syphilis in all cases of stomach trouble before resorting to operative measures, as syphilis of the stomach assumes such protean manifestations The chronic nature, the exacerbations at night absence of free hydrochloric acid and gastric achylia are presumptive evidence of syphilis of the stomach especially when the Wassermann test is positive In one of his own cases the syphilitic stenosis of the pylorus in a tabetic was accompanied by a negative Wassermann He comments on the exceptional frequency of syphilis of the stomach at Rio he encountered six cases last year The general practitioner is the one who sees these stomach cases first and hence his proper differentiation of them is of paramount importance Clark is convinced that the number of cases which escape detection is considerable They may run an entirely latent course until suddenly they entail severe hemorrhage This occurred in two of his cases In two others there was likewise severe hemorrhage but it had been preceded by violent pains in the stomach None of these four patients succumbed to their profuse hemorrhages Another patient had had severe hematemesis on three occasions in the course of several months before the syphilitic nature of the trouble was suspected Treatment as for syphilis was then given, and there has been no further trouble from this cause during the three years since He gives an illustration of the necropsy findings in a case of supposed chronic ulcer of the duodenum After a profuse hemorrhage, operative treatment was applied and the patient died Necropsy revealed a large and ulcerating gumma close to the pylorus, adherent to the pancreas No one had thought of applying the Wassermann test In some other cases tentative mercurial treatment just before a contemplated operation, rendered the latter unnecessary

Two of his patients had been martyrs for years to chronic dyspepsia with nausea and vomiting and had run the gamut of therapeutic measures, none giving relief until specific treatment was tried when a cure soon followed The cure has been complete during the several years to date He reports with much detail his various cases, emphasizing the differential points

94 **Progressive Neuritis with Hypertrophy**—Yokomori reports two cases of the affection described in 1893 by Dejerine as *névrite interstitielle hypertrophique et progressive* Yokomori s patients were a farmer of 74 and his son, a bank clerk of 38 The first symptoms developed in the forties and twenties a weakness in the legs, with gradual inability to hold the foot up—paralytic talipes equinus varus Atrophy of the muscles in legs and hands followed in time The tendon reflexes were all abolished, but the coordination of muscular movement was unimpaired, as also sphincter functioning Nos of the peripheral nerves could be palpated as thickened and hardened and necropsy in the first case showed that this was due to peculiar changes in the sheath of Schwann and the interfascicular connective tissue The cases are compared with the few analogous ones on record and the points differentiating them from somewhat similar nervous affections are emphasized Five plates accompany the article, one colored to show the contrast staining

96 **Blastomycotic Meningitis**—Goto's patient was a member of the legislature, 61 years old A three page clinical chart of his case is given, with three colored plates showing the necropsy findings in the brain and meninges and in the lungs of mice inoculated with the cerebrospinal fluid The main symptoms had been headache, tinnitus, deafness, persisting cold in the head anosmia and diplopia, with pains in the right leg and reduced sensibility in the right trigeminal region During the seven month's course there was no fever until toward the last, when symptoms of meningitis became pronounced From the first were noticed right abducent paralysis and atrophy of the right half of the tongue The fluid at lumbar puncture the fifth month was under high pressure and contained blastomycetes and 3 or 5 1 000 albumin No point of entry for the blastomycetes could be discovered but innumerable blastomycotic nodules were found on the pia, containing blastomycetes and giant cells in profusion

97 **Bradycardia of Thyroid Origin**—Sakai gives several charts and tables to show the course and details in a case of disturbance of impulse production, auriculoventricular automatism with pronounced bradycardia—pulse 42—all evidently traceable to irritation of the vagus nervous system The data presented demonstrate that this irritable condition of the vagus is the result of lack of the normal thyroid secretion The thyroid functioning was at a very low ebb, and the heart disturbance could be corrected at will by injecting atropin by exercise and baths or by thyroid treatment The patient was a woman of 42 who had long had an apparently ordinary goiter and complained of loss of hair and menorrhagia Sakai says that he knows of no analogous case on record in which impaired functioning of the thyroid was responsible for abnormal impulse production of this type in the heart

98 **Total Heart Block**—Atropin had no appreciable influence on the total heart block in one of Marui s two cases In the second the ventricle beat increased by eight beats, showing that even with total heart block the vagus may ve exert a certain control over the ventricle Injection of epinephrin in the first case, a working man of 59 induced the bigeminus picture, the extrasystoles with the total heart block are ascribed to stimulation of the accelerator nerves Under the influence of the epinephrin the pulse became accelerated and at the same time the rare phenomenon of interference was observed There was evidently pronounced sympatheticotony, with extreme susceptibility to epinephrin The electrocardiograms and other tracings show the peculiar features of the two cases

99 **Chemical Action of Substances in Expired Air**—Takasaki reviews the literature on the toxicity of expired air and reports personal research in this line Ikeda recently found that some substance in expired air was able to inhibit the hydrogen dioxid-splitting power of colloidal platinum Takasaki has been repeating his experiments and has confirmed his statements The substances condensed from the water with the expired air check catalysis of colloidal platinum and also of blood catalase This substance in the expired air cannot be either ammonia or carbon dioxid The inhibiting property was found least pronounced in persons with diabetes insipidus and adiposogenital dystrophy, and greatest in patients with cirrhosis of the liver The substance in question is probably formed in the gastro-intestinal tract and eliminated through the lungs On the other hand, none of the animals injected with the substance showed any signs of toxic action

100 **The Internal Secretion of the Kidneys in Connection with the Sugar in the Blood**—Itakura relates that the sugar content of the blood became much higher in an hour or hour and a half after the veins or arteries of the kidneys had been tied off The increase was much higher after ligation of the veins than of the arteries This effect was less apparent when much blood had accumulated around the kidney These facts are accepted as evidence of an internal secretion in the kidney which keeps the blood sugar within normal range Even the extravasated blood from the kidney is capable of maintaining the control Still more striking testimony is the fact that the abnormally high sugar content in the blood after ligation of the renal vein could be brought down to normal by subcutaneous injection of blood from the renal vein of another, nontreated animal

106 **High Infant Mortality in Russia**—Roumianzeff points out in his article the fact of the tremendous infant mortality in Russia He says that it is higher there than any where else in the world among civilized nations Of the five or six millions of new-born children each year, a million and a half die before they reach the age of one year In some regions of European Russia up to 600 of every 1,000 succumb, that is, over 50 per cent, in contrast to the 7 or 8 per cent infant mortality in Sweden and Norway The causes he traces to poverty, ignorance, and lack of suitable social and economic factors, combined with insufficient and improper infant nursing and care, and also the frequency of gastro-intestinal disorders in children These dangers are multiplied by severe infectious diseases, such as scarlet fever, measles, etc Measures for infant welfare and for reduction of infant mortality are now realized as matters of national importance in Russia, and have been officially taken up by the government

108 **Elimination of Sodium Chlorid in Scarlet Fever**—Ostrovsky's conclusions are as follows In the initial stages of scarlet fever there is retention of chlorids, as well as in relapses of scarlet fever, from the tenth to the twentieth day of the disease the amount of sodium chlorid eliminated rises in waves In some cases the wavelike rise is followed by a wavelike fall A surplus amount of sodium chlorid given with the food is eliminated by the patient during the two or three following days Weiss' apparatus was found very accurate and superior to any other method of which he knows for quantitative determination of the sodium chlorid in the urine

112 **Recurrence of Gallstones After Removal of Gallbladder**—Kadian reports in detail a case of cholelithiasis successfully operated on with removal of the gallbladder Six years after the operation the patient returned to the clinic with new symptoms of cholelithiasis Operative treatment was applied anew and at the second operation a new formed gallbladder was found, continuous with the common bile duct The latter contained about ten cholesterin stones (cholesterin 76 per cent and bilirubin 17 per cent) Kadian gives a review of 28 cases somewhat similar which he gathered from the literature In his case a small stone must have been, he thinks, left in the common bile duct It kept gradually increasing in size, during the six years, because of deposits of bilirubin salts The origin of the gallstones he ascribes to the liver itself True relapses with new formation of stones are exceedingly rare To prevent recurrence, the operation must include not only the removal of the gallbladder and the stones within, but opening up of the common bile duct and removal of all concretions The cystic duct must be ligated as low as possible to avoid formation of a diverticulum to form a new gallbladder No ligatures, sutures or gauze threads should be left in the duct

116 **Iodin in Operating on the Eyes**—Orechkin used 5 per cent alcoholic tincture of iodin with brilliant results in numerous ophthalmologic operations The patient's lids, portion of forehead, corresponding side of the nose, cheek and temporal region were painted with the 5 per cent tincture Moist regions and the eye secretions are dried previous to the application of the iodin solution The latter must be always freshly prepared The burning sensation caused by the iodin may be quite severe, in spite of preliminary cocainization, but disappears in a few minutes After the painting with iodin, the conjunctival sac, in operations on the eyeball is flushed copiously with a sterile 1 5,000 solution of cyanid of mercury None of the 237 cataract operations gave suppuration, while with other antiseptic methods he had suppuration in 2 per cent, with subsequent loss of the eye In 1,200 other operations on the lids and adjacent portions only in five cases was there suppuration in the sutures, and he explains this complication by the low grade of intelligence of the majority of his patients He comes to the conclusion that Grossich's method of disinfection of the operative field is the best and that it should be given preference also in ophthalmic surgery

A STUDY OF 1,153 CASES OF SCARLET FEVER

WITH ESPECIAL REFERENCE TO THEIR SEQUELAE *

LOUIS I DUBLIN, Ph D
Statistician, Metropolitan Life Insurance Company
NEW YORK

It is the primary purpose of this paper to report on an investigation into the sequelae of scarlet fever It has been possible in addition, to examine some general characteristics of the cases under review, and these, too, will be considered in the report The plan which has been followed was developed in a study of the sequelae of typhoid fever,[1] namely, to trace the condition of the survivors of the disease as far as is possible through an interval of four or five years subsequent to recovery, and to note especially the occurrence of any undue number of deaths during this period from causes which may be considered sequelae of the primary disease In the case of typhoid fever, I was able to show that, in a series of 1,428 cases in which the patients had survived the attack of that disease, the mortality during the three following years was twice as great as was to be expected from the age, sex, and color of the group This high rate of mortality resulted from an increase in the number of deaths from tuberculosis and organic heart disease In view of the well known effect exerted by scarlet fever on the heart and kidney tissues, it seemed likely that an analogous condition of high subsequent mortality might be found to prevail In any case, it was desired to measure exactly the conditions which actually arise

The records of the Visiting Nurse Service of the Metropolitan Life Insurance Company again gave us the original material for the investigation There were 1,153 cases of scarlet fever in the two years 1911 and 1912 among white persons The patients were all treated by physicians The accuracy of the diagnosis was in little or no doubt, and the records in other respects were fairly complete and trustworthy The patients were all policyholders of the company, and their whereabouts and physical condition could readily be traced during the subsequent years For those patients who died, full and comprehensive medical records were at hand for examination

Table 1 shows the distribution of the 1,153 primary cases by sex and by age period

Nearly 82 per cent of all the cases were among children between 2 and 10, the company has no policyholders in the first year of life The greatest disposition to the disease is found among children from 3 to 7 years of age, 637 cases, or 55 2 per cent of the total, were found within these five years of life The period 11 to 15 presents an appreciable number of cases, but after this period the cases are few and far between, all of them amounting to only 6 9 per cent of the total We are, therefore, concerned primarily with children In this respect our series agrees substantially with other scarlet fever series McCollom, for example, reports that 75 per cent of his patients treated at the Boston City Hospital were between the ages of 2 and 10, and 50 per cent between the ages of 3 and 7 The figures for Willard Parker Hospital cases are very similar There is apparently no important distinction in this respect between the two sexes

TABLE 1 —DISTRIBUTION OF 1 153 CASES OF SCARLET FEVER BY SEX AND AGE

Age	Males and Females		Males		Females	
	Number	Per Cent	Number	Per Cent	Number	Per Cent
All Ages	1 153	100 0	501	100 0	652	100 0
2 to 10	941	81 6	433	86 4	508	77 9
2 to 5	503	43 6	254	50 7	249	38 2
2	103	8 9	63	12 6	40	6 1
3	132	11 4	57	11 4	75	11 5
4	148	12.8	73	14 6	75	11 5
5	120	10 4	61	12.2	59	9 0
6 to 10	438	38 0	179	35 7	259	39 7
6	123	10 7	54	10 8	69	10 6
7	114	9 9	47	9 4	67	10.3
8	76	6 6	31	6.2	45	6 9
9	65	5 6	22	4 4	43	6 6
10	60	5 2	25	5 0	35	5 4
11 to 15	132	11 4	53	10 6	79	12 1
16 to 20	43	3 7	11	2 2	32	4 9
21 to 30	24	2 1	4	0.8	20	3 1
31 to 40	13	1.1			13	2 0

Not only are the children at the youngest ages more susceptible to scarlet fever, but it appears that these children also take the disease in the severest form This is evidenced by Table 2, which presents lethal rates for the number of deaths per hundred cases treated, classified by age

There were in all ninety deaths in the total of 1,153 cases, this represents a lethal rate of 7 8 per cent At age 2, next birthday, 15 5 died out of every hundred treated For the age period 2 to 5 the lethal rate is 10 1, and for the entire period 2 to 10 the lethal rate is 8 8 Thereafter the lethal rate decreases very appreciably The very high figure for the age period 31 to 40 is of no significance, since the number of

---

* The writer is indebted to Dr Lee K Frankel for his courtesy in putting the records of the Visiting Nurse Service of the Metropolitan Life Insurance Company at his disposal for this study

[1] Dublin L I Typhoid Fever and Its Sequelae Am. Jour Pub. Health 1915 v No 1

cases was only thirteen and the number of deaths one, altogether too small a group to give reliable returns

The figures for our series are again in close agreement with those of other observers The lethal rate of scarlet fever varies considerably with time and place, depending on the severity of the epidemic An average of 8 4 per cent is given by McCollom on the basis of over 37,810 cases in Boston, covering a period of twenty-eight years Some hospital figures show a somewhat higher lethal rate According to Osler, 90 per cent of all the scarlet fever deaths are of children under 10, our figure was 92 per cent As our cases were drawn from all parts of the country, no particular epidemic is unduly represented, and the findings are close to the best previously reported averages for large series of cases covering many years

TABLE 2—LETHAL RATES PER HUNDRED CASES TREATED FOR SCARLET FEVER, CLASSIFIED BY AGE

Age	Number Treated	Number Died Under Treatment	Lethal Rate per 100 Cases Treated
All ages	1 153	90	7 81
2 to 10	941	83	8 82
2 to 5	503	51	10 14
2	103	16	15 53
3	132	16	12 12
4	148	11	7 43
5	120	8	6 67
6 to 10	438	32	7 31
6	123	14	13 38
7	114	7	6 14
8	76	3	3 95
9	65	6	9 23
10	60	2	3 33
11 to 15	132	4	3 03
16 to 20	43	1	2 33
21 to 30	24	1	4 17
31 to 40	13	1	7 69

The 90 deaths showed complications in 62 cases In 11 of these there was a distinct kidney involvement Heart conditions were recorded in 7 fatal cases Pneumonia was present in 13 cases There were 4 cases of meningitis and 1 case of otitis media In 9 cases the scarlet fever was complicated by the presence of other acute infections like diphtheria or measles The other complications are few in number, and are too vaguely stated to justify special attention Among the 1,063 survivors we find similarly a record of 31 cases of nephritis, 31 cases of otitis media, 22 cases of adenitis, and 11 cases of pneumonia It is very probable, however, that in the nonfatal cases the complications were not stated as fully as could be wished, certainly not as fully as is usually done in hospital practice Osler, for example, records the presence of nephritis in from 10 to 20 per cent of his cases Heart complications are also recorded in higher proportions in other series Middle ear trouble is reported in 20 per cent of all cases by Fisher, and the same author, in a series of over 6,000 cases, records 14 per cent that had adenitis We must not infer, however, from the smaller number of complications recorded by us that the cases were less severe than is usual We have already shown that the lethal rate is very close to the average obtained by other investigators on the basis of large exposures over long periods

We are now concerned with the tracing of the 1,063 cases in which the patients survived, and we shall see whether, during the following years, the complications or impairments which they suffered really affected their chances of life to any appreciable degree There were represented, during the entire subsequent period, 3,583 years of life This means that the 1,063 persons were under observation for an average period of 3 4 years The expected number of deaths for this group of survivors was then calculated The mortality rate actually experienced by the company for corresponding age, sex and color during the years covered by the study was used as a standard According to this measure, we had a right to expect 18 6 deaths As a matter of fact we experienced only 18 deaths Far from showing a higher mortality, as was the case in the typhoid fever study, we found a death rate almost identical with the expectation based on our general mortality experience The actual mortality was 97 per cent of the expected We may, therefore, say that during the period covered by our observations the mortality of the survivors as a group shows apparently no increase Table 3 presents a comparison of the actual and expected mortality among the 1,063 survivors, classified by age period

The most favorable condition is found in the age period 2 to 5 years The actual number of deaths is somewhat higher than expected in the age period 6 to 10 (117 per cent) The deaths are considerably higher in the period 11 to 15 (244 per cent) In view of the small number of persons exposed in this age period the figures must not be considered as entirely decisive, although they are suggestive

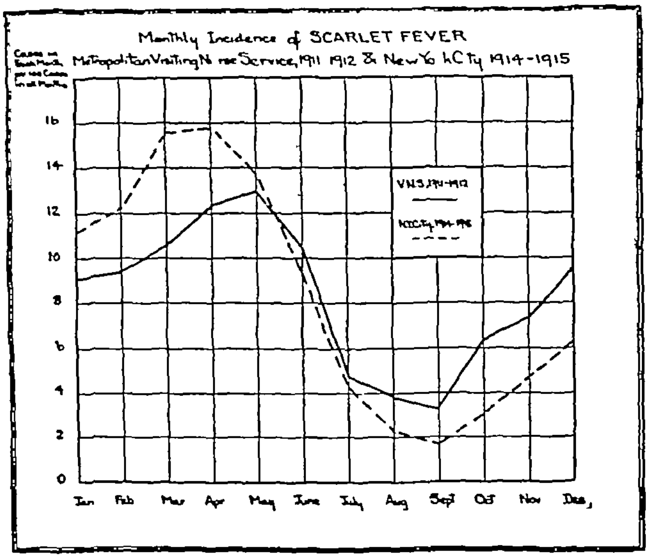
It is of interest to find that, of the eighteen deaths which occurred in the four years, three showed a record of endocarditis on the death certificates, these cases may reflect the impairment resulting from the original scarlet fever There were five deaths from respiratory diseases and four from tuberculosis The remainder were scattered among a number of causes which have no particular interest for us Strangely enough, there were no deaths from kidney diseases Apparently, among the survivors of the primary disease, the kidneys were not sufficiently impaired to cause early death

TABLE 3—COMPARISON OF ACTUAL AND EXPECTED MORTALITY AMONG 1 063 PERSONS IN FIVE YEARS FOLLOWING RECOVERY FROM SCARLET FEVER, CLASSIFIED BY AGE PERIOD

Age Period	Number of Years of Life	Number of Expected Deaths	Number of Actual Deaths	Actual Deaths per 100 Expected
All ages	3,583 40	18 61	18	97
2 to 5	908 29	9 16	7	76
6 to 10	1,614 35	6 00	7	117
11 to 15	699 53	1 64	4	244
16 to 20	194 88	0 62		
21 to 30	105 66	0 67		
31 to 40	60 75	0 52		

We are concerned, therefore, with explaining the difference between the actual experience and that which was expected on the analogy of our typhoid fever investigation A comparison of the two sets of conditions is useful, moreover, because it helps to a clearer insight into the kind of impairment which results from scarlet fever In the typhoid fever cases there was, after recovery, a marked increase in the number of tuberculosis deaths An increase was also noted in the number of deaths from organic diseases of the heart, but this was not so great In our scarlet fever cases, on the other hand, there is no positive evidence of an increase in the number of tuberculosis cases The three deaths from endocarditis are too few to justify any conclusion as to serious heart impairment in the survivors The interesting fact is the absence of deaths from kidney diseases It would seem, then (and this is confirmed by clinicians), either that impairments of the kidneys, which are so common in scarlet fever, are severe enough to cause immediate death, or that in the survivors the injurious effect is not sufficiently great to kill within the next five years Apparently, in the cases in which there was recovery, there has not been enough destruction of kidney tissue to prevent subsequent regeneration It is quite possible, of course, that ultimately there may be an increase in the expected number of deaths from kidney lesions, although such a consequence may not manifest itself until ten or more years have elapsed after the initial incidence of the scarlet fever We hope to clear up this possibility in the future

DEATH RATES FROM SCARLET FEVER



Seasonal distribution of scarlet fever cases.

Although, as I have indicated, the sequelae of scarlet fever are apparently not an appreciable factor in the mortality of survivors, it should not be overlooked that the disease itself still constitutes an important factor in child mortality The disease has not shown the same amount of decrease in frequency during the last fifteen years that has been observed in connection with other infectious diseases The death rate fluctuates about the figure of 10 per 100,000 In 1900 the scarlet fever death rate in the registration area was 10 2, in 1913 the rate was 8 7 In spite of this drop, there were a number of years in the intervening period when the rate was even higher than the 1900 figure Light is cast on the mortality conditions from this cause by the industrial mortality experience of the Metropolitan Life Insurance Company, the figures for which are presented in Table 4 These rates are new and have the particular advantage of accuracy The count is correct not only for the number of deaths from scarlet fever, but also for the number of persons living in the various classes by which the mortality is enumerated We are able to present rates by age, period, sex and color

TABLE 4—MORTALITY EXPERIENCE FROM SCARLET FEVER 1911 1914 3 778 DEATHS CLASSIFIED BY COLOR, BY SEX AND BY AGE PERIOD DEATH RATES PER HUNDRED THOUSAND METROPOLITAN LIFE INSURANCE COMPANY—INDUSTRIAL DEPARTMENT

Age Period	Persons	White Males	White Females	Colored Males	Colored Females
All ages	11 1	13.8	11.2	2 7	2.2
Under 5	64 4	71 1	64 7	17 4	21 9
5 to 9	29 5	27.3	31 0	10.3	7 3
10 to 14	8 0	7.2	9 7	5 3	2 4
15 to 19	3.5	3.8	3 7	0.5	2 2
20 to 24	1.8	1 1	2 9		0 4
25 to 34	0 9	0 7	1.3	0 8	0.2
35 to 44	0.5	0 6	0 5		0 5
45 to 54	0 2	0.2	0 1	0 5	
55 to 64	0 3	0.2	0 8		0 7
65 to 74					
75 and over	0 8		1 4		

The most interesting fact indicated by this table is the markedly lower mortality of the colored Generally speaking, the death rate for colored children is about one fourth that of the whites This fact may serve medical investigators as a point of departure for a study of the etiology of this still obscure disease

TABLE 5—INCIDENCE OF 1 153 SCARLET FEVER CASES, 1911 1912 BY MONTHS

Month of Occurrence	No of Cases	Month of Occurrence	No of Cases
January	105	July	53
February	111	August	45
March	133	September	36
April	141	October	71
May	140	November	82
June	119	December	108

SEASONAL DISTRIBUTION OF SCARLET FEVER CASES

Our study has also made possible a presentation of the seasonal distribution of the 1,153 cases of scarlet fever This distribution is shown in Table 5

From January the frequency of the disease rises rapidly until May, when the maximum number of cases occurs Thereafter there is a rapid drop in the number until September, which is marked by the minimum For the remainder of the year there is a rise in the curve which stops at a point which is slightly higher than that experienced in the previous January

The accompanying chart shows the seasonal distribution of these scarlet fever cases compared with the distribution of 20,984 cases reported by the Department of Health of New York City for the two years 1914-1915 The cases which were reported in each month, per thousand occurring in the entire year, are shown

The two series are clearly similar in their distribution The largest number of deaths occurs, in both, during the months of April and May, and the fewest number in September It is during the summer months that the cases are rarest in their occurrence, and it is quite possible that this condition is correlated with the absence of children from school during the vacation period With the opening of school in September the number of cases begins to increase rapidly, reaching the maximum in the spring Of course, attendance at school is not the only factor, since certain respiratory diseases show a similar seasonal distribution, and are clearly subject to the weather conditions

THE MUNICIPAL HOSPITAL AS A FACTOR IN CLINICAL TEACHING *

HANAU W LOEB, A M, M D
Dean, St Louis University, School of Medicine
ST LOUIS

Since the establishment of the first medical school in America, there has been a tacit understanding that the patients in public institutions should be placed at the disposal of medical colleges for clinical instruction While this understanding has been more or less indeterminate and has been, in fact, frequently set aside by public or private action, there has been in the main an admission of the right of medical education in this particular

This right has not infrequently been subject to revision or abrogation by officials temporarily in power, in some cases the exercise of the right has been attended with difficulties, complex in character, and in other cases the right was established or implied by statute For instance, as far back as 1876, the St Louis city charter, adopted that year specifically gave to the medical schools of the city the authority to conduct clinical instruction in the city hospital, but denied it in the Female Hospital, which was at that time a social evil hospital

Until the adoption of the staff plan, six years ago, the St Louis City Hospital was under the direction of a superintendent, often the mayor's personal physician, who was clothed with the business management of the institution, subject, however, to considerable political pressure The superintendent was the sole arbiter of the medical care of the patients of the hospital, unhampered by any interference on the part of politics, which, however, still continued to be impressively concerned with the business side of the institution

The consequence was that each four year period found a new incumbent, generally without business or institutional experience, with an overweaning desire and hope to achieve triumphs in surgical practice when the turn of politics brought forth his successor In a few instances — by accident, let us say — a trained surgeon secured the position, but these were the few hopeful exceptions As to the nonsurgical care of the patients in the early days, it was either ignored or placed entirely in the hands of the interns Later, however, a more or less irregular attendance on the part of a few earnest physicians of the city, without official appointment or without official authority, supplemented the service and improved it to a great extent Later still, the medical service was placed under the charge of one of the assistant superintendents

This type of organization, if so it can be called, offered very little hope for clinical instruction in the municipal institutions of St Louis, and as a consequence the private hospitals of the city were utilized by the better medical schools, the municipal hospitals being either ignored or used only in a perfunctory and certainly in an unsatisfactory manner At one time, there were eight colleges using the city hospital, and as many as eight lectures delivered in one week on one poor patient — without harm to him of course, for he was not examined by the multitudes of eager aspirants for knowledge in the eight different colleges, but he was *looked at* from a distance by eight more or less sleepy crowds and *talked about* by eight professors, who were prepared to lecture on the patient, even if their examination consisted of a few minutes' previous conversation with the intern in charge

Instruction was practically limited to amphitheater talks and discussions by men who had no professional charge of any patients in the hospital, and bedside work was absolutely prohibited

I have given this short sketch of the teaching history of the St Louis City Hospital because, in great measure, it is the history of such institutions in other cities, somewhat modified, it is true, by the local environment and by the reactions consequent on local medical activity

Apart from the futility of appointing an inexperienced man to be both administrator and sole surgical operator in an 800 bed hospital, there existed the stupid provision of changing him every four years for another, who was almost necessarily less trained in hospital administration, if not in operative work

While admitting the doctrine of equality before the law, the appointing power does not and often cannot exercise a proper discrimination between the qualified and the unqualified, owing to the exigencies of political administration and party patronage As a consequence, when, by way of exception, a really good man was made superintendent, it was due either to an unusual ability and foresight of the authorities with a strong regard for justice to the community or to a strange concatenation of circumstances that political sleight of hand sometimes sets in motion

Where the staff plan has been in evidence, the scheme of appointment has been subject to the same objection as in the other plan, for the qualification of the appointees was not the basis of selection except in rare instances, generally the designation of the degree "Doctor of Medicine" satisfied the question of qualification, and political relations determined the appointment But in the last ten years a tremendous change has taken place, brought on perhaps by the drift of medical education and perhaps also by an awakening sense on the part of the profession which has influenced the powers that be in the proper direction

The truth of this is shown in the responses to the following question, which I submitted, among others, to the Class A schools of this country "Have you more control over the material in the municipal hospitals today than you had ten years ago?"

Some of the colleges in the larger communities where there has been no need of the municipal hospital for the purpose of clinical instruction, and institutions such as Tulane, Texas, etc, which have had for years the fullest control over the municipal hospital, note no improvement in this regard This is also true of the colleges in New York which share the material at Bellevue Hospital The answers of the other colleges, however, indicate a tremendous increase of the college influence, and manifest the growing tendency all over the country of the feeling that the best interest of patients in municipal hospitals is conserved and promoted by a closer relation with medical colleges both in treatment and in clinical instruction

About six years ago, the system in vogue in St Louis for many years was changed, and the municipal hospitals were placed under the control of a hospital board and hospital commissioner In place of a single superintendent with both medical and administrative functions, the medical control was vested entirely in a staff of physicians who were appointed by the board and a superintendent was placed in charge of the administration

---

* Read before the Association of American Medical Colleges, Chicago, February, 1916

This was a tremendous step in advance, for such attending physicians as were connected with medical colleges had under this new arrangement the necessary control over their patients to use them for clinical instruction if they so desired While, here and there, men were appointed without the proper qualification, a group of men were gathered together eminently fitted for the work Naturally, the college men were in larger number than those not attached, and it was therefore possible to utilize the institution better for clinical purposes than ever before

The new charter adopted in 1914 made the foregoing plan a part of the organic law of the city, except that the director of public welfare was given general direction taking the place of the hospital board, which was abolished, and the hospital commissioner was given full power of appointment

While the latter arrangement was a great improvement over the preceding system, there still remained much to be achieved, more particularly with respect to organization The positions on the staff belonged, as it were, to the attending physicians and not to the colleges, and hence the colleges were obligated for the material to the attending physicians, and were dependent on their good will for clinical instruction, so far as the municipal hospitals were concerned This was, to say the least, not conducive to efficiency or coordination of teaching Furthermore, the appointments were for two years, and therefore there was no assurance that even the best clinical instructor would be continued in office for a longer period This made it impossible either to perfect an efficient organization or to establish a definite policy While enthusiasm and activity of a corps of instructors may make up for deficiency of organization, these good qualities may be in time supplanted by indifference or neglect

To obviate this and to provide a plan of appointment subject to less pressure from friends and political associates, the hospital commissioner (Dr C H Shutt), with the consent of the director of public welfare, accepted a plan which was the result of numerous conferences with the deans of the Washington University and St Louis University medical schools — a plan which could not have been adopted if the representatives of these two institutions and the hospital commissioner had not kept constantly in mind the civic responsibilities brought about by the situation

The plan adopted is as follows The hospital is divided as equally as possible into three units For Unit 1, the appointments are made, without reserve, on nomination of Washington University, for Unit 2, they are made similarly on nomination of St Louis University, and for Unit 3, the hospital commissioner appoints whom he pleases, no instructors in either of the universities being eligible Units 1 and 2 are entirely under the control of the respective universities, and thus it has been possible to establish the rank of appointees which was impossible heretofore Hence it is that in each of these units there is a complete organization in each department, and each clinician's position in the unit is dependent on the university controlling it Furthermore, as a later development, definite members of the resident staff have been attached to the different units, and definite wards have been assigned

While the outside unit cannot possibly effect an organization similar to that of the teaching units, especially in view of the equality of rank and the absence of institutional control of the clinicians, much has been done to establish its efficiency In the assignment of wards, Units 1 and 2 have properly given first selection to Unit 3

The immediate policy of the staff is under the charge of an executive committee composed of two representatives from each unit, and I may say that there has been the utmost harmony in all of its transactions Although the plan has now been in operation for but eighteen months, it has been productive of good results, not only as to clinical teaching, but also in efficiency, which is even more important Without giving the details of this improved order of things, which must be manifest to any one who understands the value of organization, I content myself with mentioning that during the year ending Dec 1, 1914, there were 5,238 visits made by the staff, whereas during the following year under the new plan there were 10,930

It is true, the continuance of this whole plan is dependent on the will of the hospital commissioner and the director of public welfare, but we feel that the value of a consistent organization to the patients of the municipal hospitals will become increasingly manifest, and that the influence of the two universities cooperating in this great civic and educational activity will be potent enough to cause its permanent adoption

This same plan can be adopted in other large centers provided the medical colleges of the highest class work together to the end that public charges in municipal hospitals shall be under the direction of a staff that is appointed on the basis of a definite policy, which comprehends only the highest ideals of medicine, always bearing in mind that provision must be made for the large number of medical men who are not connected with medical colleges, and who possess ideals and qualifications equal to those of the instructors in recognized medical schools

The dean of a certain medical college writes me of his most excellent plan by which, under private arrangement made with the constituted authority, the college makes the appointments He asks me not to mention the name of the institution for fear that, if it were known, the privilege would be lost Without knowing the local conditions, I venture the opinion that publicity in this regard, fortified with the civic and professional validity of such practice, will do more to perpetuate it than the secret understanding, which is likely to be abrogated in time, as the arguments for its continuance have been carefully concealed

In administering the St Louis University unit, we have kept in mind the two important organization requirements, first the patient's welfare and second the student's opportunity We have felt that these could be best achieved by organizing each department on the basis of a head, responsible to the institution, with associates and assistants under his direction As our appointments are not limited to any specified number, except as to the minimum, we can exercise our best judgment as to the personnel

It was soon determined that the organization in prospect required far more of the clinician's time than under the previous plan For this reason, it was found advisable to provide compensation for some of the men in medicine and surgery, at the same time requiring them to spend from three to five hours a day in attendance on patients and in instructing students assigned to work at the City Hospital

At present, three of the attending physicians and three of the attending surgeons are paid, not an extravagant amount, but at least enough to justify them to give the time which the service and instruction require In addition, there are two men in medicine and two in surgery who are not paid Our purpose is to increase the number of men who are paid for part time, and to add men with proper compensation in these two departments who will give their full time to the work At present, no provision has been made for compensation in the specialties, in fact, under our conditions, it is hardly necessary, still, it would not be amiss if full or part pay men were provided in children's diseases, obstetrics and nervous and mental diseases

It is thus seen that our institution is provided with 350 beds in the municipal hospitals, entirely under our charge, with paid instructors in medicine and surgery, with definite assignment of wards under our own members of the resident staff, and with authority to train our students according to the opportunities presented

I would not have it understood that this implies that the condition is absolutely satisfactory or that there are not many difficulties in the way of an ideal accomplishment, but at any rate we are approximating the rational solution of the question

The type of clinical material in municipal hospitals in America has not been altogether the best for teaching purposes, especially in the surgical service The variety is limited, and the stay of patients in the hospital is too short, for few, except those who find it impossible to go elsewhere, apply for admission to the city hospital Why should it be otherwise in an institution which can have no definite policy, which has no consistent organization, and which is administered by men who, whether they are qualified or not, are in the main appointed by those who do not know and cannot know? Why should the people, if they can avoid it, place themselves under the care of physicians whose appointment is not on a qualification basis, and whose tenure of office does not depend on the presence or absence of their efficiency or attention to duty?

How much better is it to hold the universities or medical colleges of the highest class responsible for a definite portion of a hospital, bringing to the institution the influence, the organization and the efficiency which this plan assures, not by concealing its potentiality, but by openly advocating the measure on the well grounded, easily proved claim that it is the best for the people and for the hospital A general adoption of this plan (particularly if the clinicians are paid by the universities) must be followed by an improvement in the character of the clinical material and a more perfect fulfilment of the function of the city in respect to its indigent wards

Under present general conditions there is an economic waste of thousands of patients in municipal hospitals who are lost as material for instruction to students in medicine Add to this the vast amount of funds required by the more fortunately endowed institutions to furnish their students with material for study How much less money would be required and how much more material would be available, if these same institutions could perfect a proper organization of their legitimate share of the municipal hospitals!

Nor may we evade this issue by saying that the municipal hospitals are necesarily a part of the municipal political machine, and therefore unworthy of our concern Our obligation as educators and citizens demands of us that we exert our utmost to the end that these institutions be made to serve their highest functions in medicine and pedagogics

Politics and practical politicians have the greatest regard for the demands of the people, and they listen with keen ears to those who are honestly working for the public good For this reason, cooperation and public propaganda of the good to be accomplished by this plan of organization, efficiency and consistency of policy will be followed by its adoption and continuance, without any opposition or with only the feeblest protest on the part of those who are looking for personal perquisites

The result will be that American medical institutions, like the European, will be able to bring the highest ideals of medicine into municipal hospitals, and to provide their students with what is absolutely essential, if the physician of the future is to be the beneficiary of the best sources of instruction in his profession

A "GROUP STUDY" PLAN FOR A DIAGNOSTIC TEAM ACTING AS A LABORATORY FOR THE PROFESSION *

FAYETTE WATT BIRTCH, M D
SAN FRANCISCO

Since the idea of pay clinics, group study, diagnostic team work, medical attention to the middle class, and the limitations of physicians have been frequently and openly agitated in the medical journals and the lay press, it is deemed advisable to present for consideration the San Francisco St Luke's Hospital Clinical Club's plan for diagnostic group study in general hospitals This plan provides a type of group consultation for the general practitioner with the aim of preserving the advantages of specialism and eliminating the disadvantages

There are a few private pay clinics in this country where patients may go and be completely examined by a number of specialists At these clinics the majority of cases remain under the care of the doctors of the institution, passing out of the hands of the referring physicians St Luke's Hospital, San Francisco, is the only institution reported to have organized specialists to act as a laboratory for diagnostic purposes, returning the patient after investigation to the referring physician with a protocol of the findings and recommendations for the treatment of the case

Two of Dr Richard C Cabot's articles[1] are of interest in this connection His ideas in the first appear to be sound in theory, but the subsequent discussion of the paper clearly indicates that no definite plan for the solution of the problem was received The second article undoubtedly contains many ideals far in advance of present medical practice, but in it are many things which would have been better unsaid Dr Cabot makes destructive criticism of the profession without balancing it by constructive criti-

---

* Read before St. Luke's Hospital Clinical Club, San Francisco, March, 1916

[1] Cabot, R C The Need of Pay Clinics for Persons of Modera Means, Am Hosp Assn, 1915, xvii, 411 Better Doctoring for Less Money, Am Mag, April, 1916, p 7

cism He has sought to teach the laity to distrust the general practitioner, without giving the doctor a concrete plan for the correction of his faults If Dr Cabot will continue his articles on this subject in medical journals and construct a plan whereby group study can be practically carried out by the profession, he will do much toward obtaining better medicine for the masses

This new era in medicine is very young the medical universities are not yet teaching this type of medicine, they have not even accepted it, and in fact, there is no definite instruction to be had on the subject The method of group study now employed in hospitals, by referring the patient from one department to another without joint discussion of cases by the heads of these departments, is open to as severe a criticism as Dr Cabot applied to the methods of the general practitioners But publications on these imperfections which will stimulate the laity to pass laws and regulations on medical matters, before the profession has had an opportunity to study the problems and make recommendations, will prove detrimental to the best interests of progressive medicine

It has not been long realized that the three great classes of patients, the rich, the poor, and the middle class, are receiving quite different medical attention The rich man, while he is able to pay for the services of a large number of high-priced specialists, presumably gets the best medical consideration, but unfortunately the highly paid specialists are individuals who are not organized, and their work is not correlated Consequently, consultations are often perfunctory and unsatisfactory to both physician and patient The pauper, on the other hand, gets the very best that medicine has to offer He goes to the free clinics, where all branches of medicine are represented, and is carefully examined by the various clinicians The individuals of the middle class, constituting about 90 per cent of the sick, are getting the worst medical care They cannot afford to pay large fees for high class specialists, nor will they accept charity They are compelled to accept incomplete examinations, erroneous deductions, and, what follows inappropriate treatment The great mass of the people, however, will not endure this long The solution of the problem will soon be found, and it will come as the result of search from an economical, if not from a humanitarian, standpoint

Dr E V Knapp, our pathologist, has aptly said in an unpublished paper

> Specialization is a necessity depending on human mental limitation If a clinician had a mind sufficiently endowed by nature, and sufficiently cultured by study to be able to appreciate all that is known about anatomy, surgery, pathology and all other divisions of medicine and he also had at his disposal time to make examinations of his patient in each of these branches, he would then have a most comprehensive, correlated clinical picture, but each division of medicine has developed so extensively that it is impossible to ascertain full knowledge of any one Furthermore, no individual could cover all divisions of medicine in all cases even though he had the ability to do so Consequently the general practitioner is no longer able to depend upon himself completely to guide his patient through any obscure illness

Specialism, however, has many disadvantages The specialist often views the cases from his branch of medicine to the exclusion of others The physician who interprets the condition of his patient, partly through written reports of the specialists who have not considered the patient as a whole, will frequently draw false conclusions These reports might be added to or subtracted from, if the specialists had viewed the case from all angles Consultations are also expensive and tend to make doctors employ them only when they seem indicated If group consultations could be a routine procedure, frequently pathologic conditions which are not suspected would be found The great disadvantage of the present day consultations with specialists is that they seldom meet to discuss their findings, and the case is rarely reexamined in the light of new evidence, remaining hazy and incomplete

Realizing their limitations and the disadvantages of the present day consultations, the profession in this vicinity, nearly three years ago, organized the San Francisco St Luke's Hospital Clinical Club for the purpose of remedying such conditions There were no guides and no landmarks, and a new trail had to be blazed It was decided to meet once a week to discuss cases, work them over, and try various plans of study Cases were studied single handed, in groups, by recommendations, by referring to specialists, and in every conceivable way, until at last "group study" was decided on as a partial solution of the difficulties Here is an outline of the method used

A diagnostic section was organized out of the San Francisco St Luke's Hospital Clinical Club This section consists of ten men, each having special training along some particular line The members of the profession refer obscure cases to this section for diagnosis These patients are placed in the hospital for observation, and each member of the diagnostic team makes an individual examination and a written report of his findings At noon each day the team meets to discuss the cases If the case is not clear at the first consultation, further investigation is recommended, and any new discoveries are reported the following day This method of procedure is continued day after day until some conclusion is reached The physician who referred the case is asked to be present at all of these consultations Finally, the patient is referred back and a written report of the findings and recommendations for treatment are mailed to the attending physician Thus the specialists make of themselves a diagnostic laboratory

All of this work is being done by the diagnostic team for a fee commensurate with the patient's income The amount collected is not sufficient to pay for the time of the clinicians However, the good that is being accomplished by this method of study and the educational returns for each member of the team in daily discussion with his colleagues amply repays the clinicians

In our experience the success of a plan of this kind depends briefly on the following conditions The diagnostic team must accept, from the profession, cases for investigation at a price consistent with the income of the patient, cases should be examined by all the members of the team, the results of their findings must be written, the specialists meet in daily consultation over the cases, and investigations continue until all possible evidence is discovered The case is returned to the physician who sent it and a report is mailed, together with the conclusions and suggestions for treatment

The results to be expected from such a scheme are these The general practitioner will gladly accept it the good influence of the family physician will be preserved, medical men in the community will take advantage of the daily discussions and gradually broaden their point of view of medicine, this method of group study will maintain the advantages of specialism and do away with the disadvantages Clinical reports from this work bearing on these predictions are now being prepared for publication

It may be said that the type of group study as now practiced in general hospitals is unsatisfactory The assignment of cases to departments for treatment is often determined by the patient's complaint without previous investigation by the various departments, which is comparable only to the methods employed by the general practitioner Group study to be profitable must not only provide for the treatment of the complaint which causes the patient to seek advice but also aim at the discovery of hidden departures from the normal in order that proper therapeutic and prophylactic measures may be recommended to the end that the individual's future health may be conserved

St Luke's Hospital

THE TREATMENT OF INTERNAL HEMORRHOIDS, BLEEDING SPOTS AND VILLOUS TUMORS OF THE RECTUM BY THE HIGH FREQUENCY CAUTERY *

JOHN A HAWKINS, M D
PITTSBURGH

No matter what the argument, there will always be a number of people who will balk at the word "operation" In the palliative treatment of hemorrhoids the best that can be expected is relief, as the name implies, and the degree of this palliation is speculative If the piles are of the external variety, whether the tumors are inflamed or not, the subcutaneous injection of a 2 per cent solution of cocain, alypin or other local anesthetic, followed by excision and the loose horsehair suture of the edges of the wound, will give good results, and the patient scarcely realizes he has had an operation

In the treatment of the internal variety the quacks have always been popular, in that they risk infection, abscess and other dangers when they inject their patients with phenol (carbolic acid) solution There is no doubt that they have cured some patients, but it is equally true that they have produced intense suffering, and in many cases their treatment has led to fistula I recall one case in particular of a patient who, after injection for hemorrhoids, developed a fistula with an opening larger than the index finger Strange to say, the quack "got away with it" However, the lucky patient, who escapes the dangers mentioned, and obtains a cure without the dreaded operation, forgets his suffering and sings the praises of the one who cured him I am not decrying the radical operation for hemorrhoids Excision and suture quickly disposes of these tumors But for the patient who cannot or will not take an anesthetic the method I describe will efficiently, though slowly, give a radical result, and the patient need lose no time from his work

Several years ago Beer of New York described a method of removing villous tumors, or papillomas, of the bladder by the use of the high frequency current of Oudin, that is, the single pole current, and cited cases Later, he published case reports of other operators, among which he included some of my work This method is now a recognized mode of treatment for these tumors About two years ago I tried this method in the treatment of a case of bleeding from a nevus growth in the rectum The usual treatment of this condition has been the application of pure nitric acid by means of a glass rod, with the possibility that the acid might not limit itself to the growth The result of the application of the high frequency current was excellent This success led me to try it in a case of internal hemorrhoids My patient was a man who was willing to try anything except an operation He had one tumor larger than a pecan and several small ones It took ten treatments covering three months (Less than half that time would now be necessary) The cure was radical and the man did not lose a day from his office This was in September, 1914 Since then I have operated on quite a number of other patients with internal hemorrhoids, in many of whom bleeding was the chief symptom

In this work I use the Wappler portable transformer, with Krafft spark gap, and the 110 volt alternating current This current, stepped up on the rheostat to number 3 or 4 and a very narrow gap, gives a very hot spark at the aluminum electrode, which quickly sears the flesh, with the odor of burning meat A foot switch is convenient, but not absolutely essential An electrode of $\frac{3}{32}$ inch aluminum rod set in a hard rubber handle and bent to an angle of 135 degrees with the handle, and covered with thick-walled rubber tube, can easily be procured This electrode is about 4 inches long, and to make a large burning surface a small shepherd's crook should be made on the end One can readily try out its cauterizing effect on callus found on nearly every doctor's hand since the advent of the automobile With the patient in the knee-elbow position and sway-backed, a toothpick around which is wound absorbent cotton, making an applicator $\frac{1}{4}$ by $1\frac{1}{2}$ inches, is soaked in a 4 per cent solution of any of the previously mentioned local anesthetics and pushed into the anus, being allowed to remain there for about ten minutes, while the apparatus is made ready The anal tube or speculum is now introduced, the light attached, the anus wiped out if necessary and the electrode applied (I use a Martin's anal tube, to which is attached my own lamp arrangement, although even a head mirror may be used)

The application of the electrode differs from that of the electrocautery The electrocautery is applied to tissue after it becomes red, but with the high frequency electrode the cauterization is accomplished in the gap or arc between the electrode and the tissues The electrode is of aluminum and does not even become discolored It is applied to the tumor and then carefully withdrawn until its highest efficiency is secured, as determined by the eschar and smoke One tumor is thoroughly burned longitudinally with the axis of the bowel When this tumor has become black, another is given a light dose, that is, one tumor is burned quite energetically and one or two lightly at a sitting, and then the burned area is painted with liquid petrolatum, or, as I prefer, with oil of eucalyptus, 1 in 8 of the oil, and no further treatment of the parts is given for two weeks, or until the sloughs have come away and the parts are clean There is little or no pain ten

---

* From the Surgical Department, South Side Hospital

minutes after a treatment, and the local anesthetic lasts that long One can hardly believe the statement that the pain of the high frequency burn is so transient, but the burn is severe for a few minutes unless anesthesia is secured

Having used this method of treatment for several years in the removal of bladder tumors and for nearly two years in the treatment of rectal hemorrhages and tumors, I cannot speak too highly of the results

ACUTE PELVIC APPENDICITIS

WITH CASES IN POINT

EDMUND A. BABLER M D
Surgeon to Deaconess and City Hospitals
ST LOUIS

An acutely infected appendix is the most frequent and one of the most serious acute abdominal lesions demanding surgical attention The laity is not alone responsible for the present-day mortality being higher than it should be, this is due in part, I think, to the frequency with which the appendix lies in the pelvis, thereby changing the classic picture of acute appendicitis so materially that we do not always recognize the source of the symptoms sufficiently early to avoid disaster

We all know how deceptive may be the symptoms in acute simple appendicitis When the appendix lies in the pelvis the picture may be even more deceptive, since the clinical manifestations are largely dependent on (1) the site of the appendix, (2) the severity and duration of the infection, (3) the presence or absence of adhesions, (4) the state of health of adjacent organs, and (5) the character of the treatment The cases herein reported emphasize these facts

Pain is invariably a prominent symptom It differs from the classic in being situated lower in the abdomen and more diffuse in character, in many cases it is referred to adjacent organs The absence of localized pain at McBurney's point is one of the most frequent causes of our failure to recognize the disease In many cases the pain will be most severe just above and to either the right or left of the pubes In several of my cases it was referred to the bladder, while in others the patient complained of persistent severe pain in the epigastrium Sudden cessation of severe pain may signify perforation, in any case it does not necessarily mean improvement

Abdominal rigidity is nearly always present, but the impressive feature in these cases is the finding that both recti are rigid, the rigidity is not limited to the right rectus, although it usually is more rigid than the left because the site of inflammation is usually to the right The left rectus may, however, be more rigid than the right This is a frequent cause of confusion in making a diagnosis in these cases

The characteristic point tenderness midway between the umbilicus and the anterior superior spine of the ileum, as described by McBurney, is absent because the field of action has shifted to the pelvis This finding is quite misleading unless the practitioner recalls that the appendix frequently lies in the pelvis Pressure made over McBurney's point may not cause any pain whatsoever, pressure over a corresponding point on the left may incite severe pain Rectal examination may show an inflammatory mass in the pelvis

Vomiting is usually not a persistent symptom When the inflammatory process is advancing upward it may be more or less constant It usually follows the initial pain of onset, but may precede the pain If the appendix becomes adherent to coils of small intestines causing ileus, vomiting becomes a very prominent and persistent symptom

Flexion of the right leg is usually absent in cases of acute pelvic appendicitis The reason is obvious Late in the disease, however, both limbs will be found flexed

The pulse, temperature and blood findings do not differ from those observed in classic cases

The diagnosis of acute pelvic appendicitis requires a careful consideration of the previous history, the mode of onset of the present attack and the shifting of the symptoms from the epigastric to the hypogastric and inguinal regions instead of to midway between the right anterior superior spine of the ileum and umbilicus, the physical findings will eliminate primary involvement of the adjacent pelvic organs The mere fact that the symptoms began as an appendicitis and the picture still resembles the clinical manifestations of a diseased appendix, although the characteristic McBurney point tenderness, etc, are absent, should lead us to make a provisional diagnosis of acute pelvic appendicitis This is especially true if examination then shows absence of disease of the adjacent pelvic organs, an immediate operation is called for It is not necessary to have the classic picture of appendicitis to make a diagnosis of appendicitis The preponderance of the symptoms, and the fact that the patient is suffering from some acute pelvic lesion which is not due to an acute pus tube, should warrant immediate attention We all know that when the appendix is adherent to the bladder or to the peritoneum overlying the ureter, the patient will often complain of bladder symptoms and the urine may contain blood and pus (Cases 1 and 4) We also know that the appendix may become adherent to the rectum or ovary, or possibly to an infected tube, thus causing symptoms of acute infection in the respective organ

In any case the clinical manifestations indicate clearly an acute abdominal lesion demanding early attention If in doubt as to the diagnosis, the physician should place the patient in Fowler's posture, administer saline proctoclysis according to Murphy's method, and withhold all purgatives, food and opiates Purgatives only increase peristalsis and the possibility of perforation An enema is preferable If the symptoms persist at the end of six hours, a consultation should be held

The treatment of acute pelvic appendicitis does not need comment We all know that immediate operation saves practically every case of appendicitis The contention that we should wait until the inflammatory process becomes localized is simply preposterous, Murphy has shown how erroneous is this thought Morphin administered before operation kills many patients I do not think it necessary for the practitioner to make an accurate diagnosis before he recommends operation in these patients presenting the clinical picture of an acute abdominal condition We really best serve the patient by calling surgical consultation in these cases before the distended abdomen, the persistent, agonizing pain, the high temperature, the vomiting, the rapid pulse and the anxious expression tell the tale of too much "watchful waiting"

CASES IN POINT

A brief report of a few of the recent cases will suffice to impress the picture in these cases of acute pelvic appendicitis

Case 1—*History*—A R, white man, aged 30, gave a history of previous attacks of pain in umbilical region, nausea, pressing desire to urinate, followed by vomiting, severe pain just above pubes and passing of bloody urine The present attack began twenty-four hours ago with sudden severe pain in umbilical region followed by nausea, vomiting and shifting of the pain to just above the pubes Dr Westrup found patient suffering intensely, both recti were intensely rigid, pressure over lower abdomen incited desire to urinate even though the patient had been catheterized, pulse 90, temperature 100 On the following morning the symptoms had somewhat subsided Dr Westrup diagnosed case as one of appendicitis

Examination—When I saw patient twenty-four hours after onset the abdomen was soft, but pressure near insertion of the right rectus muscle caused considerable pain and a desire to urinate, no tenderness at McBurney's point, temperature 99 pulse 80, and symptoms subsiding, leukocyte count 14,000 Small mass found on rectal examination

Operation—Patient felt so well on the following day that he wanted to go home but finally consented to operation The appendix was found gangrenous and partially surrounded by omentum and adherent to the right posterior surface of the bladder

Case 2—*History*—O H, white girl, aged 13, was suddenly seized with chill and fever followed by severe pain in umbilical region and vomiting three days prior to consulting Dr Washington, the usual home remedies had been given without avail, her menstrual period was due and she thought her trouble was possibly due to this

Examination—Dr Washington found pulse 120, temperature 104, abdomen distended and very rigid, there was no point tenderness in area described by McBurney, in fact, pressure over left rectus induced more pain than pressure over McBurney's point, bowels had moved but the pain was so severe and paroxysmal in character that patient complained a great deal I saw the patient a few hours later and was impressed by the absence of pain at McBurney's point, the diffuse character of the pain and its location just above the pubes, also by the diffuse rigidity and high temperature and pulse rate Patient was sent to the hospital, where a blood count showed leukocyte count of 18,000

Operation—Median incision confirmed Dr Washington's diagnosis, the appendix was gangrenous and lying low down in the pelvis, numerous coils of distended small intestine were found glued together by fibrin

Case 3—*History*—A F, white woman, aged 26, had been complaining for two days of discomfort just above pubes, the pain was not constant or severe, but the usual home remedies had not brought relief Patient had vomited once, bowels had acted and she walked to the bath room without discomfort Dr Bewig saw the patient a few hours before I did, he found pulse 78 and temperature 100 The abdomen seemed slightly distended, but patient insisted that such was not the case, both recti were flaccid, deep pressure above the pubes caused pain, whereas pressure over McBurney's point was negative

Operation—Two days later the patient consented to operation because the pain had persisted and she was afraid of appendicitis Median incision showed a swollen, slightly gangrenous appendix lying low down in the pelvis, there were no adhesions

Case 4—*History*—M G, white man, aged 32, gave history of previous attacks, and had been told that he had appendicitis The present attack began thirty-six hours before with severe pain in lower abdomen, pain became more or less constant, vomiting frequent

Examination—Expression was somewhat anxious, abdomen distended, both recti intensely rigid, tenderness over greater part of lower abdomen, rectal examination negative, pulse 110, temperature 102, leukocyte count 18 000, urine contained pus and casts

Operation—Immediate operation revealed swollen gangrenous appendix lying behind and to the right of the bladder, the omentum was adherent to base of appendix and bladder

Case 5—*History*—H H, white man, aged 21, had been sick three days Illness began with cramplike pains in lower abdomen followed by nausea Purgative had been given but bowels had not acted The fact that examination did not show rigidity of right rectus and McBurney point tenderness confused the medical attendant Patient entered hospital with a diagnosis of intestinal obstruction

Examination—Expression was very anxious, abdomen greatly distended, legs flexed, pulse 130, temperature 101, leukocyte count 16,000, mass in pelvis, both recti intensely rigid, patient presented usual picture of advanced peritonitis

Operation—A gangrenous perforated appendix was found lying in pelvis, intestines intensely congested and of a mahogany color, parietal peritoneum intensely congested, the pelvis was filled with pus

COMMENT

Numerous additional cases would only tell the same story We must not expect the classic picture in these pelvic cases I am confident that the mere dissemination of the knowledge that it is possible to have appendicitis without the classic McBurney point tenderness, right rectus rigidity, etc, and that the appendix frequently lies in the pelvis and may cause left sided pain and left rectus rigidity, etc, will be the most potent factor in bringing these cases of acute pelvic appendicitis to surgical attention sufficiently early to enable us to reduce the mortality to the minimum

---

CIRCUMSCRIBED PURULENT LEPTOMENINGITIS DUE TO FRONTAL SINUSITIS

SAMUEL LEOPOLD, M D
Instructor in Neurology and Neuropathology, University of Pennsylvania, School of Medicine
PHILADELPHIA

Circumscribed leptomeningitis of rhinogenous origin has been rarely noted by the neurologist, and only in the last decade or so by the rhinologist The literature on intracranial, oculo-orbital and cerebral complications secondary to disease of the accessory sinuses of the nose has become so extensive that more recent writers have concerned themselves with complications arising from individual sinuses

Purulent leptomeningitis from frontal sinusitis may occur with or without brain abscess, it may be in association with pachymeningitis or with an extradural abscess

The seat of the lesion is chiefly on the convexity of one or both frontal lobes, with varying involvement of other portions of the brain The symptomatology is that of sinus disease with accompanying meningitis Three forms may be distinguished, a sudden apoplectic, quickly terminating, a slow, insidious, protracted type, and an intermittent form, with long interval before the meningitic attack

Case 1 illustrates the sudden onset of meningitis, after a period of intermittent sinus trouble

CASE REPORTS

Case 1—R K, errand boy, aged 14, was seen by Dr G on Nov 20, 1914 The boy was suffering with pain in the head, the right eye was swollen and there was pain over the right orbit

He gave a history of repeated head colds In the latter part of September 1914, he developed a severe head and chest cold, which continued for two weeks and was accompanied by profuse purulent discharge from the nose

On November 14 he contracted fresh head cold, and on the next day he complained of pain shooting through the head, eyes and teeth The following day there was swelling around the right eye and slight exophthalmos

At the time of the patient's first visit he complained of pain over the right frontal sinus region, intense frontal headache, and there was closure of the right eyelid, with some bulging of the eyeball

Examination of the right frontal sinus showed pus A portion of the middle turbinate was removed and considerable pus drained away On Saturday he was examined again His symptoms had improved, but protrusion of the eye was still marked The swelling over the right orbital ridge was incised, but no pus was found The next day he developed severe headache over the frontal and occipital regions and a deeper incision over the frontal sinus released considerable pus

Several days later he developed paralysis of the opposite side of the body, of the leg chiefly The temperature became from 102 to 104, pulse of from 90 to 100 A Killian operation was performed There was a great quantity of pus, and the septum between the sinuses was found necrosed, so the sinuses were entered and cleansed The temperature dropped to normal and the patient felt much better For two days his condition was good The next day his temperature rose suddenly, he became stuporous, and his pulse became rapid and weak.

I first saw the patient the afternoon of the day he died He was stuporous, showed paralysis of the left leg and partial paralysis of the left arm He had ankle clonus and the Babinski sign, with rigidity of neck.

A diagnosis of circumscribed purulent leptomeningitis was made but operation was not advised, owing to the moribund condition of the patient He died two hours later

Necropsy—On opening the cranial cavity the dura was found smooth and glistening, but bulging. On opening the dura, a purulent exudate was found over the right frontal lobe, extending as far as the postcentral gyrus A small exudate was noted over the right temporal lobe and over the superior surface of the cerebellum The pus had also escaped into the right middle fossa The anterior and posterior fossae were free The frontal sinus was free of pus, but showed a thick clot of blood and some granulation tissue The diploic veins were markedly congested The longitudinal sinus was filled with pus The roof of the orbit showed necrotic bone, and there was pus in the orbit The right anterior and posterior ethmoid sinuses, as well as the sphenoid sinus showed normal mucous membranes

Pathologic Summary—The pathologic findings revealed a purulent leptomeningitis, limited chiefly to the right frontal lobe, extending as far as the central gyri There was some basal meningitis and a small exudate on the superior surface of the cerebellum The longitudinal sinus was filled with pus Necrotic bone was found in the orbital roof at the juncture with the ethmoid

Case 2 illustrates sudden onset without showing any localizing symptoms, death occurring within a few days I had the opportunity of studying only the brain The clinical notes were obtained from the hospital record

The patient, a young woman of 22, was taken ill with cold in the head, severe headache, some nausea and vomiting There was no record in the history referring to nasal trouble On admission to the hospital her condition was that of semistupor, alternating with delirium The pupils were equal and reacted to light and in accommodation There was some rigidity of the neck, and the knee jerks on both sides were exaggerated Kernig was obtained on the right side The Babinski sign was absent on each side Lumbar puncture showed cloudy cerebrospinal fluid polymorphonuclear cells 89 per cent lymphocytes 10 per cent No tubercle bacilli or meningococci were found Patient could be made to talk but remained usually in semistupor The pulse was from 100 to 140, and the temperature varied between 100 and 103 Death occurred in five days

Necropsy —On opening the skull, the dura was found smooth and free from adhesions The veins were congested Removal of the dura showed a thin, purulent exudate over the convexity of both frontal lobes, reaching as low posteriorly as the central convolutions, and extending laterally to the sylvian fissure on each side The remaining surface of the brain as well as the base, was free from exudate Examination of the frontal sinuses revealed a congestion of the mucous membrane, but no free pus There was some exudate over the cribriform plate of the ethmoid, and the longitudinal sinus was distended with blood

Diagnosis—Influenzal meningitis following frontal sinusitis and ethmoiditis

Pathologic Summary —Purulent leptomeningitis, confined chiefly to the convexity of both frontal lobes, frontal sinusitis, and ethmoiditis

These two cases, as well as a study of the literature, show that the symptoms, as revealed in Case 1, are frequently preceded by weeks, or even months of nasal catarrh, with frontal headache, or, as in Case 2, they may occur after only a few days, following an attack of influenza The edema and discoloration of the eyelid, with tenderness over the orbit, as in Case 1, frequently precede the cerebral symptoms when disease of the wall of the sinus or orbit is present The frontal headache is present in nearly all cases, though pain in the head is not limited to that region The pulse and temperature are not characteristic Rigidity of neck and Kernig's sign, though noted in both my cases, are not frequent symptoms Paralytic symptoms are noted usually in a later stage of the disease Irritability and restlessness, alternating with clouding of the sensorium, are sometimes the only meningitic symptoms present, and death sometimes comes, as in Case 2, before the development of paralytic symptoms

The pure meningitis following frontal sinus disease is less frequent than brain abscess, but much more frequent than thrombophlebitis This is analogous to Korner's statistics on otitic meningitis In 140 cases analyzed by Gerber, there were sixty-five cases of brain abscess, to fifty-one of meningitis

The explanation of this phenomenon depends on the route of infection, which may be direct, through the interstices or necrotic walls, or indirect, through the venae perforantes of the sinus and orbit, or through the lymphatics According to Gerber, the most frequent route in the production of leptomeningitis is through disease of the dura, following disease of the posterior wall of the sinus Disease of the anterior wall, with thrombosis of the longitudinal sinus, may produce it indirectly, and disease of the inferior wall, with necrosis of the orbital roof and thrombophlebitis of the veins, may also indirectly produce leptomeningitis It is possible that the lymph channels may play as important a part as the diseased walls and veins Zwillinger, in some recent experiments on animals, has investigated the relation of the perimeningeal lymph spaces — the subdural and the subarachnoid — with the lymph vascular nests of the frontal sinus, and has shown that a direct connection exists This may explain the route of infection in Case 2, as well as in many others reported, in which the route was not clearly demonstrated. Logan Turner thinks that they play a subordinate role, for the operating table and necropsies have shown the infection spread as the result of caries of the contiguous bone

There have been few cases reported in which operation led to recovery Gerber found three out of fifty-one cases of meningitis, those of Herzfeld, Piffl and

Luc To this we would add the case of Spiller, Shields and Martin, reported in 1908 This case, not noted in the reports of Gerber and Onodi, was the first case with recovery reported in America The recovery in this case was supposed to be due to exposure of the diseased area to the air, but recent studies in experimental meningitis, by Kopetzky and Haynes, show that relief of intracranial pressure can cause recovery

It seems that in many cases the dura escapes involvement, that incision is necessary in all cases in which absence of lesions on the surface is noted This holds true, not only for the meningitic cases, but also for the subdural and frontal lobe abscesses

The failure of recovery in most of these cases may be traced to several factors — the virulence of the infection, frequently streptococcic, with rapid termination of the case in several days (cases of Mahu, Wertheim and others), the absence of meningitic symptoms (cases of Blessig-Tiling, Lendentu and others), the failure to recognize the underlying process sufficiently early, and finally, the presence of an apparently normal dura, preventing further operation

---

FREE TUMOR DIAGNOSIS AS A FUNCTION OF STATE PUBLIC HEALTH LABORATORIES *

LEVERETT DALE BRISTOL, M D
Professor of Bacteriology and Pathology, University of North Dakota, School of Medicine, Director, State Public Health Laboratories
UNIVERSITY, N D

This study and report is based on a survey of the various states in regard to the existing facilities for the laboratory examination of specimens of suspected cancerous tissue Through the agency of this report, it is the intention of the American Society for the Control of Cancer to consider the need for a general extension of such facilities under public auspices, and the means by which it may be accomplished

METHODS OF INVESTIGATION

To obtain information as to what is being done in the different states at the present time, a questionnaire was sent to the directors of the various state public health or hygienic laboratories, and in some instances to the secretaries of the state boards of health Answers to the following questions have been received from all of the forty-eight states

1 Do you make pathologic diagnosis of tumor tissue in your state public health laboratory, or in any other state institution?

2 If these examinations are made, is the work done free of charge, or what is the amount of special fee asked for same?

3 Do you believe that such work should be done free of charge, either by state public health laboratories or other institutions in each state, as an important aid in the campaign against cancer?

In order to determine the value of free tumor diagnoses made by a state public health laboratory from the standpoint of the practicing physician and surgeon, a second questionnaire was sent to a large number of North Dakota doctors The free diagnosis of tissues by the public health laboratory is required by law in that state, and has been carried on for nine years The following questions were asked

1 Do you send your suspected tumor specimens to the state public health laboratory for diagnosis?

2 If not, who makes your pathologic diagnoses?

3 Do you believe the average practitioner is prepared to make accurate microscopic diagnosis of cancer?

4 Do you think that early diagnosis is an important step in the prevention and cure of cancer?

5 Have the tumor diagnoses of the state laboratory been satisfactory in the past?

6 Do you believe that the doing of such work, free of charge, is of value as a public health measure in helping to control cancer?

RESULTS OF INVESTIGATION

Present Facilities for Pathologic Examinations in State Laboratories —Of the forty-eight states, twenty-four have facilities for the diagnosis of suspected cancerous tissue either in their state public health laboratory or in some other state institution, while twenty-four do not attempt such work Table 1 gives the names of such states

TABLE 1 —FACILITIES FOR TUMOR DIAGNOSES IN PUBLIC LABORATORIES

States Which Have Facilities	States Which Do Not Have Facilities
North Dakota, Wisconsin, Indiana, Minnesota, South Dakota, Mississippi, Iowa, Florida, Alabama, Arkansas, Pennsylvania, New Hampshire, New York, Missouri, Michigan North Carolina, Rhode Island, West Virginia, Kansas, Louisiana, Vermont, Delaware, Texas, Oklahoma Total, 24	Nebraska, Illinois, Virginia, Connecticut, Oregon, Colorado, Montana, Massachusetts, Washington, Idaho Maine, Ohio, Nevada, Maryland California, South Carolina, New Jersey, Georgia, Kentucky, Utah, Wyoming, Tennessee Arizona New Mexico Total, 24

Of the twenty-four states which have facilities for such work, nineteen carry on the work in their public health or hygienic laboratories, while five do the work in their state university laboratories of pathology or preventive medicine Table 2 gives the names of such states

TABLE 2 —METHOD OF MAKING TUMOR DIAGNOSES

States in Which They Are Made in State Public Health or Hygienic Laboratories	States in Which They are Made in State University Laboratories
North Dakota, South Dakota, Kansas, Vermont, Louisiana, Michigan, Indiana, Wisconsin, Mississippi Florida, Alabama, Pennsylvania, New Hampshire, New York, North Carolina, West Virginia Rhode Island, Delaware, Oklahoma Total, 19	Iowa, Minnesota, Arkansas, Missouri, Texas Total, 5

Of the twenty-four states which have the facilities mentioned above for making tumor diagnoses, five charge specified fees, six charge all persons except indigents, and thirteen make no charge in any case Table 3 gives the names of such states

Value of Free Tumor Diagnosis as an Aid in the Campaign Against Cancer —General Opinions of State Authorities From information available, it seems that opinions of authorities differ somewhat as to whether or not tumor diagnoses should be made free of charge either by state public health laboratories or other state institutions, as an important aid in the campaign against cancer Table 4 gives the ideas of the various state authorities on this point, showing that more are in favor than against the plan, in all instances these are the personal opinions either of the director of the laboratory or of the executive officer of the state board of health

---

* Report of a committee (consisting of Dr F C Wood, Columbia University, Dr James Ewing, Cornell University, and Dr L D Bristol, chairman, University of North Dakota) appointed by the American Society for the Control of Cancer

TABLE 3—CHARGES FOR MAKING DIAGNOSES

States Charging Special Fees for Tumor Diagnoses	States Charging Fees for All Except Indigents	States Charging No Fees for Tumor Diagnoses
West Virginia, New Hampshire South Dakota ($3), Wisconsin ($5), Michigan (free if specimen is sent by health officer) Total, 5	North Carolina ($5), Arkansas ($5) Alabama ($5) Indiana, Vermont ($2) Texas Total, 6	North Dakota Rhode Island, Missouri New York Pennsylvania Florida, Mississippi Iowa (if gross specimen is sent for teaching purposes), Minnesota, Louisiana (work done only for indigents) Kansas (work done only for indigents), Delaware, Oklahoma Total, 13

TABLE 4—OPINIONS AS TO VALUE OF FREE DIAGNOSES

States Approving the Plan of Free Tumor Diagnoses as an Aid Against Cancer	States Not Approving the Plan of Free Tumor Diagnoses as an Aid Against Cancer	States Giving No Opinion
North Dakota Kentucky Rhode Island, Missouri Maine, New York Idaho Washington Montana, Colorado, Pennsylvania Connecticut, Florida Illinois Mississippi Delaware Tennessee Indiana Michigan Louisiana (for indigents), Utah Vermont, Kansas Texas Arizona Oklahoma Total, 26	Iowa Georgia New Jersey, South Carolina California West Virginia Maryland Nevada Ohio Massachusetts, Oregon Arkansas, Alabama Virginia, Nebraska, Wisconsin Minnesota South Dakota Total, 18	North Carolina New Hampshire, Wyoming New Mexico Total, 4

The chief arguments received from the sources named above against the free diagnosis of tumor tissue in state laboratories are as follows

1 "Diagnosis of tissue for cancer is merely a private consultation and is not regarded as public health work"

2 "The plan would savor too much of state medicine"

3 "As a rule the appropriation for the state laboratory does not warrant the doing of more work, and tumor diagnosis should not interfere with the diagnosis of the so-called communicable diseases"

4 "There is danger of spreading cancer cells into other parts of the body by the excision of small specimens for diagnosis"

The arguments in favor of the free diagnosis of tumor tissue as an aid in the campaign against cancer may be summarized as answers to the foregoing four objections

1 Surgeon Carroll Fox of the U S Public Health Service says, in regard to the diagnosis of tissues for the presence of malignancy by state public health laboratories 'Such work is the legitimate work of the health department The ultimate object of all health officers is to prolong life, and to secure this result in the case of cancer, an early diagnosis is necessary It is, therefore, only right that the health officer, through his diagnostic laboratory, should lend all the assistance possible" This also is the opinion of a large number of other authorities who look on cancer as a public "menace" to be attacked by public officers, with public money

2 From the foregoing point of view, if it is the duty of the health officer to prevent premature death from all causes, it is as much his duty to prevent death from cancer as from tuberculosis For this reason, facilities for the diagnosis of suspected cancerous tissue should be offered free of charge in a state laboratory, just as facilities are offered for free sputum examinations without the cry of "state medicine" being raised

3 It is to be conceded that tumor diagnoses should not interfere with the work more strictly related to the communicable diseases, and the latter should always have priority Furthermore, it is not to be expected that such pathologic work can be carried on without sufficient appropriation to warrant it This is not an argument against free tumor diagnosis in public health laboratories, but is simply an indication that the people of the state should be educated to the point where they will be willing to appropriate more money to cover this extra work

4 It must be admitted that there is some chance that by cutting through healthy tissue into a malignant tumor, for the purpose of obtaining a specimen, metastases may be more rapidly spread But in a large percentage of cases the advantage gained by a microscopic diagnosis is very much greater than the risk of spreading the disease by its proper removal for such a purpose On this point Sondern has briefly stated the conservative opinion of a committee of the American Society for the Control of Cancer

> In the removal of tumor tissue for diagnosis, the advantage of such microscopic examination, as well as the danger of aggravating the disease by this procedure, must be considered In many cases the advantage of diagnosis outweighs the danger of removal of tissue for this purpose, and the procedure is justified in the opinion of the majority The necessity for this may be determined by the skill of the clinician Opposed to the procedure in general is the danger of aggravating the condition by the excision, and this varies according to the nature and the position of the growth To cut through the skin into a malignant tumor of the breast in order to remove a piece for examination is generally discountenanced Errors in diagnosis result from the excision of inflammatory tissue on the margin of a tumor when the section does not include tumor tissue, this being most frequent in the breast and prostate Incisions into actively growing, deep-seated malignant tumors should be avoided, as this may disseminate infection through the vessels, may permit extension or accelerate growth by relief of capsular tension There is little danger, however, from the proper removal of tissue from any superficial growth of the skin or mucous membrane Crushing or kneading malignant tissue should be carefully avoided under all circumstances

Admitting the foregoing statements, and giving wide publicity to them does not argue against the doing of such diagnostic work in public laboratories as an aid in the campaign against cancer It simply means that physicians and surgeons should use judgment as to the specimens which they wish to remove for diagnosis

We do not desire to argue against the value of frozen section work, or against any physician making his own pathologic diagnosis *if he is qualified to do such work*, any more than we would argue against his making bacteriologic diagnosis of sputum or throat cultures if he has had sufficient training to be accurate

Other points have been raised by various authorities in support of the value of tumor diagnosis in public health laboratories, the most important of which are

"It would tend to raise the general tone of surgical practice among men who have no hospital or laboratory affiliation"

"It would tend toward the diversion of material from strictly commercial laboratories, some of which are known to be grossly incompetent from the standpoint of their pathologic work "

Even to educate the public and the profession to *demand* a confirmation of a clinical diagnosis by a microscopic finding after operation would be of inestimable value in the recording of accurate vital statistics relating to cancer, in assisting the physician or surgeon to make reliable clinical diagnoses in the future, and in protecting the public from cancer quacks who always shun the microscope It is difficult to collect a fee for a pathologic diagnosis after an operation has been performed, hence the value to the public and the profession at large by the doing of such work free of charge in public health laboratories If clinical diagnoses were thus improved and cancer quacks were thus eliminated, the death rate from cancer would fall Furthermore, if accurate mortality statistics are of value in combating all diseases (including cancer), and if the state health department is chiefly responsible for gathering such statistics, it would seem that it might be of great value even for the state to *require* the sending in of pathologic specimens from all persons dying of suspected, or clinically diagnosed, malignant disease It is obvious that such required work would have to be done free of charge by state laboratories under the direction of competent pathologists

Opinions of Physicians in One State in Which the Plan of Free Tumor Diagnosis Has Been Carried on for Nine Years As a final argument in favor of our report, it may be of interest to give a few facts concerning the working of this plan of free tumor diagnosis in the public health laboratory of the state of North Dakota during the nine years since the laboratory was opened

Replies to a questionnaire (outlined previously under "Methods of Investigation") were received from 175 physicians and surgeons from all parts of the state Of this number, 125 send all of their removed tumor specimens to the state laboratory, ten send some of their material, and thirty-five do not send any of their specimens to that laboratory, while five give no information on this point

Of those not sending their specimens of tumor tissue to the state laboratory for diagnosis, twelve make their own pathologic diagnoses, twelve send their specimens to commercial laboratories outside of the state, eight send their tumor tissue to some other surgeon of recognized ability in pathology, and three to a university pathologic department outside of the state

Practically all (170) believe that the average practitioner in such a state as North Dakota is not qualified, nor has he the facilities, to make accurate microscopic diagnosis of cancer Nearly all (168) agree that an early diagnosis is an important aid in preventing the spread of cancer, and in curing the disease Of 175 physicians who answered the questionnaire, 170 thoroughly approve of the doing of such work, free of charge, in a state laboratory as a public health measure in helping to control cancer With a few exceptions, practically all who have sent their specimens to the state laboratory have been satisfied with the diagnosis as made In one or two instances the pathologic diagnosis did not coincide with the subsequent clinical history, but the few complaints made were chiefly based on the length of time occasionally necessary before a diagnosis could be received in parts of the state far removed from the laboratory

Since the opening of the North Dakota Public Health Laboratory in 1907, about 1,000 specimens of tumor tissue have been examined free of charge, the number of specimens the first year (1907-1908) being twenty-four, while the number for 1914-1915 was 218, thus showing a decided growth in the amount of tumor diagnostic work demanded of the public health laboratory

Undoubtedly the same results and opinions as given above would be obtained from the majority of states which have been undertaking such work, if a canvass of the practitioners of each state could be made

RECOMMENDATIONS

Based on the foregoing study, the following recommendations are submitted as worthy of consideration in the campaign against cancer

1 So far as consistent with local conditions, facilities should be offered under public auspices in each state for the diagnosis of tissue suspected of being cancerous Preferably, these should be made free of charge

2 The logical place for the doing of such work is the laboratory of the state health department It is not to be supposed that such work will be given the preference over other work now being done by these laboratories

3 To cover this work, in those states which have no such facilities, additional money should be appropriated

4 Judgment must always be used by surgeons in the removal of suspected cancerous tissue for diagnosis, and the value of a microscopic diagnosis should appear to outweigh the risk involved before such a procedure is adopted

---

VESICAL DRAINAGE

HISTORICAL REVIEW AND PRESENTATION OF A NEW APPARATUS *

EDWIN G DAVIS, MD
Assistant Resident Urologist, Johns Hopkins Hospital
BALTIMORE

The numerous forms of apparatus that have been devised for the purpose of disposing of urinary drainage following suprapubic cystostomy are evidence of the difficulty of the problem When we consider the conditions to be met, it is hardly to be hoped that an entirely satisfactory apparatus is possible, if by this we mean an apparatus that will permit no urinary leakage whatever, from the time of operation until the fistula is healed The method of choice is that which most nearly approaches this ideal efficiency, which requires the least attention and which causes the patient the least inconvenience In addition to the above requirements, the apparatus should be reasonably inexpensive and not too elaborate

BRIEF REVIEW OF METHODS PREVIOUSLY DESCRIBED

Of the various forms of apparatus, the simplest is a rubber tube through the suprapubic wound draining the urine into a receptacle beneath the bed This method works well temporarily, but the impossibility of maintaining a tight fit makes it unsatisfactory, because good siphon action depends on a constant supply of fluid and the exclusion of air from the bladder The first mention of the suction exerted within the bladder by a column of urine descending in a tube was made by Chiene[1] of Edinburgh in 1880 His article, however, referred, not to suprapubic drainage, but to drainage through the urethra by means of a retention catheter, the siphon action being dependent on the fact that the lower end of the drainage tube was immersed in a bottle of carbolized water, which overflowed into a basin Clogging of the tube with mucus was prevented by "raising the bottle night and morning in order to make a back-flow, which cleans the instrument" When this natural siphon is used for suprapubic drainage, a loop or a U-bend in the descending arm, which has been frequently described, is an improvement, because here the urine collects until a sufficient quantity has accumulated to descend in the form of a solid column, or fluid piston, which exhausts the air behind it, thus producing intermittent suction within the bladder Even up to the present time there appear in the literature occasional articles[2] calling attention to this natural siphon method of suprapubic drainage, and claiming for it advantages over other methods on account of its simplicity Burckhardt[3] in 1889 solved the problem of suprapubic drainage by making also a perineal incision and inserting a tube He stated that for five years he had made a practice of combining perineal drainage with every case of suprapubic cystostomy, following a method first used by Frere Côme (Jean Baseilhac) in the eighteenth century

---

* From the James Buchanan Brady Urological Institute

Numerous modifications have been described of the form of apparatus dependent in principle upon the suction exerted in a tributary tube by a column of water descending through a vertical tube from an overhead reservoir Such forms of apparatus are familiar to all This principle was first applied to surgery by Potain[4] in 1869, who used siphon suction for the drainage of empyemas The earliest available description of such an apparatus applied to suprapubic drainage was that of E H Fenwick[5] in 1888, who says, "An irrigating can is placed on a chair at the bedside, and its tube, with a clip affixed to regulate the outflow, dropped into the chamber under the bed The drainage tube from the bladder is then connected with it at an acute angle" An improved apparatus, utilizing the same principle, was described by Cathcart[6] of Edinburgh in 1895, and a modification of this the following year by W W Keen[7] of Philadelphia, who acknowledged Cathcart's priority This was challenged by Dawbarn,[8] who described his own apparatus immediately after Keen's publication, stating that he had made use of it for four years Referring to Cathcart's apparatus, he further stated that the idea of siphon drainage did not originate with Cathcart in England, but was first used in America about 1875 by Dr Snow, a dentist in Buffalo As a matter of fact, Cathcart and Dawbarn were both preceded by Fenwick and also by Spehl,[9] who in 1889 described a "siphon-laveur de la vessie" Since 1895 modifications have been described by Heaton, Walker, Wacobarn, Clerc-Dandoy, Connel, Hamilton, Chenoweth and others

These methods are all essentially similar, in that they employ an overhead reservoir of water which is refilled at intervals, the tube descending from the reservoir being connected by a T to the tube from the bladder They differ in their methods of mechanically interrupting the flow from the reservoir, with the object of producing intermittent siphonage Chenoweth's[10] apparatus combined irrigation with drainage Clerc-Dandoy[11] employed a urethral catheter for continuous irrigation of the bladder, the excess of fluid being drawn off by a suprapubic siphon Kenyon and Poole[12] in 1909 described methods of making use of suction for various purposes in the operating room, and four years later Kenyon[13] described the application of the same principle to postoperative treatment The form of suction was that produced by a filter pump or by a steam ejector, the suction being piped from the pump to the operating room or to the ward, and distributed along the baseboard to several beds This form of suction was used not only for suprapubic drainage, but also for the drainage of various wounds from which the discharge was profuse and irritating to the skin, as in the case of fecal fistula In order to render the excessive suction harmless, he devised an outer perforated tube, embodying the same principle as that described by Heaton[14] in 1898, which surrounded the inner suction tube in the wound, thus providing for a free circulation of air and preventing contact of the wall of the cavity with the suction tube Heaton says "The fluid, as fast as it collects in the cavity, trickles through the perforations of the outer tube and is then sucked up by the open end of the inner tube"

Kaczkowski[15] in 1899 used the same suction method, combined with a dumbbell-shaped rubber balloon, which was inserted into the suprapubic wound and then inflated, the suction catheter passing in through the center The idea was that the balloon approximated the bladder wall and the abdominal wall, preventing urinary infiltration Probably the most elaborate suction apparatus is that of Chetwood,[16] who in 1914 described a low-speed motor and pump constructed specifically for the purpose The motor and pump are run continuously, the amount of suction being reduced by means of a needle valve between the pump and drainage bottle, the lowered pressure within which is measured by means of a vacuum gage He also mentions having used a hydraulic suction pump applied to a water faucet in the patient's room and connected directly to the drainage bottle In 1915 Ballenger and Elder[17] again described the use of the hydraulic suction pump in the patient's room, combining the drainage with irrigation According to their method the tube is removed from the bladder after about ten days and

"the urine collected from the outer part of the incision under a glass bell-shaped cover held in place with adhesive strips"

The methods dependent upon other means than suction are not so numerous Fowler[18] in 1899, employing the principle of capillary drainage, used strips of gauze, one end tucked into the bladder and the other end lying on a rubber sheet, from which the urine drained into a urinal For permanent suprapubic drainage, Gerrish[19] in 1892 used a silver plate rimmed with rubber and held in place by a belt and perineal straps Through the center passed a tube which led from the bladder to a urinal For the period immediately following operation he used a flexible siphon In 1895 Dugan[20] described his modification of an S-shaped tube of hard material previously described by Senn, which retained itself in the bladder by virtue of its curve Bloodgood's[21] apparatus, devised in 1896, for both "immediate and permanent" drainage, consists of a rubber bag held to the suprapubic region by a belt, and draining the bladder through a hard rubber tube inserted in the fistula In England several forms of apparatus were described, dependent on a tightly fitting nonleak dam about the suprapubic wound Colt's[22] article in 1905 described an oval inverted cup of glass, open at the top and grooved around the base for a tightly fitting rim of sheet rubber which was cemented to the skin by a solution of pure rubber dissolved in naphtha Finckh,[23] in Germany, later reported favorable results from the use of Colt's apparatus In 1907 Irving[24] devised a celluloid cap which depended upon elastic bands around the buttocks for its tight fit around the suprapubic wound This was connected by two rubber tubes to a urinal between the patient's legs A method of cementing a perforated piece of sheet rubber to the skin around the fistula and then folding the free edges of the rubber over to form a flattened tube which conducts the urine to a bottle was described by Sinclair[25] in 1909 McKenna[26] used a double rubber apron applied to the suprapubic region, the inner surface fitting closely to the skin

VACUUM METHOD

The following is a description of the vacuum method as used at present in the James Buchanan Brady Urological Institute This apparatus I have previously described,[27] but without the improvement in the form of a mercury manometer, which acts as a safety valve, permitting air to pass either in or out of the urine bottle as occasion requires A glance at Figure 1 will give a general idea as to the principle of the apparatus Within the large bottle is a vacuum, which is very gradually decreased in strength by leakage of air, through a minute capillary glass tube, from the smaller bottle, so that within the smaller bottle there is maintained an air pressure which is slightly less than one atmosphere By virtue of this very slight difference in pressure, the urine is drawn out of the bladder, through the catheter and tube, and drips down into the small bottle, replacing the air which has leaked into the vacuum The only care necessary is to empty the urine bottle when it fills, and to exhaust the air from the vacuum bottle at intervals of not less than forty-eight hours

In the diagram (Fig 2) the relative proportions are somewhat distorted for the sake of clearness The bottles V and U have a capacity of 8 and 2 liters, respectively The larger (V) is known to the trade as a two-gallon, narrow-mouth packing bottle, and the smaller is an ordinary two-quart mineral-water bottle Bottle V is provided with an air-tight, four-hole rubber stopper through which pass two L-shaped pieces of glass tubing, one straight piece and one T Bottle U has a two-hole stopper with glass tubes, as shown in the diagram Catheter C, at the very tip of which there are several small perforations, passes into the bladder through the suprapubic wound, where it is held by strips of adhesive plaster, and is connected with the urine bottle by a rubber tube, with a lumen not more than 5 mm in diameter The only means of communication between bottles U and V is through the minute capillary tube (CT), which hangs within the vacuum bottle and which makes the rate of air flow from the smaller to the larger bottle exceedingly slow The small mercury manometer, which also hangs within the vacuum bottle, and which measures the air pressure within the urine bottle, will be described below

The capillary tube is shown in detail in Figure 3 The outer protecting sheath is a large glass tube about 1 cm in diameter and 10 cm long, with a constriction at the middle to support the cotton filter (F) At either end this tube resembles the open end of a vial, the glass being grooved to fit a screw-cap which holds the rubber stopper tightly in and withstands the inside air pressure Both stoppers and screw-caps are perforated for smaller glass tubing The air, coming from the urine bottle, enters through the upper stopper, then passes through the tightly packed cotton plug (F), where it is filtered, and finally forces its way through the capillary tube (CT) and on into the vacuum The capillary tube is made from a piece of glass tubing 6 mm in diameter, which is drawn and then redrawn to form an exceedingly fine, flexible, hairlike tube, the actual lumen of which varies between 30 and 40 microns, according to its length Since the making and testing of these capillary tubes is quite complicated and time-consuming, it is an economy to buy them

The manometer, with its two bulbs, as described below, is also made with some difficulty For these reasons, and on account of the inconvenience of assembling the various other small parts, arrangements have been made with the Willms Surgical Instrument Company of Baltimore to furnish the entire apparatus The method of testing the capillary tube has been previously described[27] in detail In brief, the rate of air flow through the capillary tube is determined and regulated by connecting the large end with a vacuum of known strength, and causing the air which enters through the tube to bubble through a column of water as it is drawn into the vacuum The most satisfactory caliber of capillary tube has been found to be that which permits an air flow of such a rate that seventy to eighty air bubbles per minute pass through the water, from a tube with a lumen 4 or 5 mm. in diameter, into a vacuum that will sustain a column of mercury 60 cm. in height. The piece of rubber tubing (see Fig. 2) attached to the lower end of the capillary tube obviates danger of breakage, by swinging as the bottle is carried.

The small U-shaped manometer, of glass tubing with a lumen of 5 mm., shown in detail in Figure 4, both indicates and regulates the air pressure within the urine bottle. It is placed within the vacuum bottle, as is the capillary tube, merely that the apparatus may be compact and safe from danger of breakage, but it connects directly with, and is really a part of, the equipment of the small bottle. It is shown in Figure 2 that this manometer communicates directly, by means of the T-tube, with the urine bottle, and that one arm passes in through the stopper of the vacuum bottle, while the other passes out again and communicates with the outside air. In the horizontal portion of the U-bend is a small amount of mercury (Hg), which, if sufficient pressure is exerted, will permit air to pass in either direction. Just at the lower end of the arm which communicates with the outside air is a small bulbous swelling in the glass which acts as a reservoir for the mercury. The bulb in the other arm, located about 5 or 6 cm. from the bottom, is merely to prevent the mercury from jumping out of the tube when the air bubbles through. In case the vacuum draws the air from the urine bottle more rapidly than it is replaced by urine, there will be a gradual decrease in pressure within U, as will be indicated by a very slow rise of the mercury in the arm of the manometer with higher bulb. But this pressure cannot continue to decrease, because the amount of mercury is limited, and after it has attained an elevation of about 20 mm. the supply of mercury in the lower bulb or reservoir has been consumed and air is allowed to bubble through, passing into the urine bottle. The direction of the air flow is as shown by the upper arrow in Figure 4.

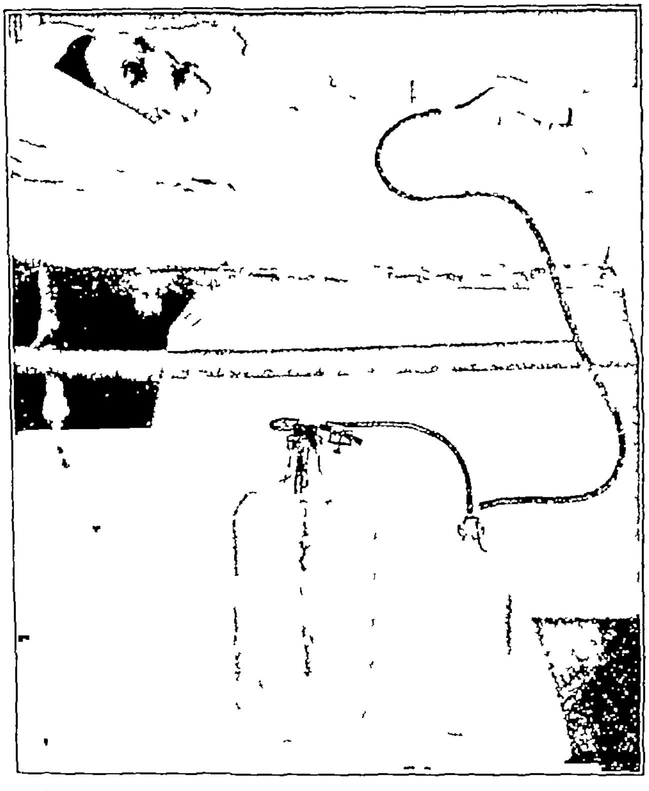

Fig. 1.—Entire apparatus in position. The bottles may be placed on the floor, or in order to facilitate the moving of the bed they may be suspended by an iron framework.

We thus have a safety valve which prevents the pressure within the urine bottle from differing from atmospheric pressure by more than 20 mm. of mercury, and which therefore prevents the catheter from exerting more than the gentlest suction within the bladder. Of course the amount of suction attainable varies directly with the amount of mercury placed in the manometer, and remains constant wherever desired. A very strong suction might be produced by making a manometer with a longer arm. For suprapubic drainage, a suction equivalent to 20 mm. of mercury, or even less, is sufficient. On the other hand, it is occasionally necessary that air pass through the manometer in the other direction, these occasions being when the rate of urinary secretion is sufficient to establish a siphon. The urine then flows into the urine bottle more rapidly than the air escapes through the capillary tube, and therefore the air pressure within the urine bottle becomes slightly more than one atmosphere. But this positive pressure does not immediately check the siphon flow, because the descending column of urine is about 40 cm. in height, which is equivalent to about 30 mm. of mercury. Before a positive pressure of more than perhaps 3 or 4 mm. has been attained, the mercury, with very little resistance, is displaced from the horizontal arm of the manometer into the lower bulb, where it spreads out, allowing the air to bubble by and escape through the open tube, and thus the siphon is permitted to continue to flow. This rapid siphon flow is only occasionally established, perhaps every other day or two with some patients, and not at all with others. The manometer, on these occasions, allows the escape of air and prevents leakage, which otherwise would occur in case the siphon flow should be checked by compressed air. In brief, the capillary tube takes care of the average urinary secretion, and the siphon action provides for any unusual excess, the mercury manometer making the siphon action possible.

During the preparation of this article I find that Perthes[28] in 1895 made use of a somewhat similar form of manometer, which permitted the entrance of air when a certain degree of lowered pressure was reached, and thus controlled the amount of suction produced by an apparatus devised for the drainage of empyemas. His manometer, however, made no provision for the escape of air, and his apparatus differed radically from the one I have described.

For renewing the vacuum, the ordinary laboratory hydraulic pump or filter pump (Fig. 6) is used, bottle V being disconnected from bottle U and carried to the pump, which may be located anywhere in the hospital. This filter pump is inexpensive and may be purchased from any laboratory supply house, together with a rubber-lined coupling which slips on to any water faucet, or, if a more permanent fixture than that shown in Figure 6 is desired, it is well to use a coupling which attaches to the faucet by means of screw threads. To exhaust the bottle the screw clamp is opened and the tube attached to the pump, the water being allowed to run perhaps seven or eight minutes, or any length of time in excess of this The amount of time necessary, of course, varies with the size of the pump and the rate of the water flow When the bottle has become sufficiently exhausted, a peculiar sucking noise is produced, similar to the sound caused by screwing the screw clamp shut while the water is running The vacuum thus produced, which is of sufficient strength to sustain a column of mercury 750 mm in height, will last at least forty-eight hours, providing the lumen of the capillary tube is of the correct diameter Even after three days the vacuum bottle will not have become quite filled with air, and on two occasions, when the bottle was forgotten and allowed to run seventy-two instead of forty-eight hours, there was no leakage After forty-eight hours, however, leakage might occur, because the rate of air flow, and therefore the amount of suction, varies inversely with the amount of air which is present in the vacuum bottle For this reason the routine of renewing the vacuum every forty-eight hours was adopted

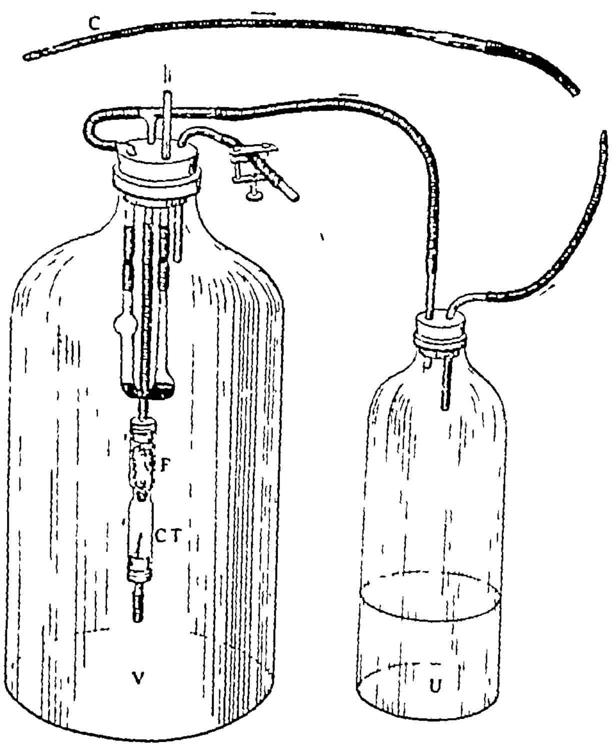

Fig 2 —Diagram showing relations of various tubes Arrows indicate direction of air flow

The management of the apparatus is as follows At the time of operation a small soft rubber tube or a large catheter, very near the tip of which are several small perforations, is left in the bladder In case a prostatectomy has been done and there is much bleeding, it is necessary to use a large tube at first, and then substitute a smaller one later on A tube with a lumen 5 mm in diameter serves the purpose admirably, and, if there is no bleeding, may be used from the start Bladder irrigations will prevent clogging of the tube with mucus and pus, but these are seldom necessary oftener than every three or four days, unless there is a marked cystitis Most cases will drain well with no irrigations at all When the tube or catheter is changed, which need not be more frequently than every three or four days, it should be replaced well down into the bladder It should fit the sinus approximately, but, in order to insure perfect drainage, it need not fit tightly Smaller catheters are substituted as the fistula granulates, one even as small as a 14 F draining perfectly well The rubber stopper must be kept tightly in the urine bottle Care must be taken that the latter be emptied before it overflows, as otherwise urine would be drawn over to the vacuum bottle and the capillary tube clogged and ruined For the same reason it is essential that, of the two glass tubes ending within the urine bottle, the one from which the urine drips should be the longer

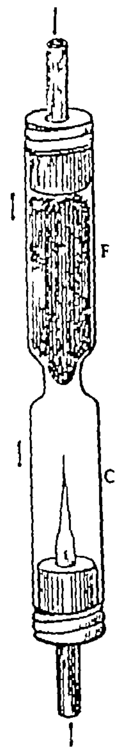

Fig 3 —Detail of capillary tube, with outer protecting glass sheath, F, cotton filter, CT, capillary tube

One may test the apparatus by simply compressing the tube connecting the two bottles, which has the same effect as a clogging of the catheter, and which should cause a slow rise of the mercury in the arm of the manometer up to a height of about 20 mm, and then a quick fall, due to the passage of an air bubble Failure of the mercury to rise indicates either that the vacuum needs renewal or that the urine bottle has been allowed to overflow, thus clogging the capillary tube The capillary tube and the manometer are delicate and should be handled with care When once suspended within the vacuum bottle, they are safe and may remain permanently undisturbed A small square pad of cotton or gauze, with a slit cut to the middle for the catheter, has been found to make a convenient dressing, strips of adhesive plaster holding both pad and catheter in place Allowing the patient to sit up in a chair makes the drainage none the less perfect, the bottles being placed upon the floor by the side of the chair A smaller, but shorter-lived, vacuum bottle has been used, and the patient allowed to roll about in a wheel chair with the two bottles upon the foot-board While the patient is in bed, an iron framework is used, which suspends the bottles a few inches above the floor and permits the bed to be moved about with more convenience

As the case records below show, the incisions are kept, not almost dry, but absolutely dry, and without a drop of urinary leakage for weeks at a time The complete lack of moisture is shown by the fact that the dressing becomes adherent to the granulation tissue about the catheter Another feature is the very slight amount of suction, which is just adequate and no more and which permits the use of an unprotected suction catheter in the bladder with no damage to the mucosa and no discomfort to the patient The catheter may therefore be decreased to a very small size as the fistula granulates, the interval between the removal of the catheter and the final healing being thus reduced to a minimum Although the above detailed description is complicated, the apparatus itself is in a simple and compact form, and is automatic, being enclosed within a bottle which need never be uncorked It requires minimum attention, and its action is not dependent on a water supply in the room, or on a motor In all cases the sutured portions of the wound healed by first intention

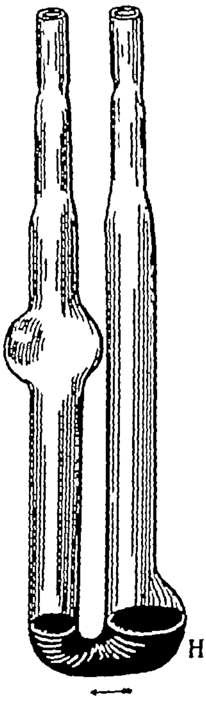

Fig 4 —Detail of mercury manometer Air may pass through in either direction, as indicated by the arrows, Hg, mercury

CASE REPORTS

The following six cases are the last of a series of twenty-two An accurate record of leakage was not kept in the other seventeen, but they did not differ materially from these here presented

Case 1—The patient entered the hospital with a suprapubic cystostomy done elsewhere for drainage The prostate was removed by the perineal route and the vacuum drainage apparatus connected to a No 14 French catheter in the suprapubic fistula On the tenth day there was drainage of urine over the abdomen due to a clogging of the catheter with mucus which was the only urinary leakage during the entire convalescence from either the suprapubic or the perineal wound The suprapubic catheter was left in position for a period of thirty days, being changed every fourth or fifth day Following its removal the edges of the tiny fistula approximated there being no urinary leakage whatever

Case 2—A suprapubic cystostomy was done on account of a recto-urethral fistula Continuous drainage was kept up for twenty-nine days During this period the abdomen became wet once on the fourteenth day due to a clogging of the catheter and with this exception remained entirely dry at all times The catheter was changed every fourth or fifth day, there were no bladder irrigations

Case 3—A suprapubic cystostomy was done on account of a periurethral abscess From the viewpoint of efficient drainage this result was the most unsatisfactory of the entire series probably because of the fact that the patient was continually delirious and in constant motion He frequently tampered with the drainage tube and in fact pulled the catheter out of the bladder several times The urinary leakage was quite marked on the third fourth fifth and sixth days and also on the eleventh and seventeenth Drainage on the other days however, was perfect There were no bladder irrigations The patient left the hospital on the eighteenth day

Case 4—A suprapubic prostatectomy was done following an incomplete perineal prostatectomy at another clinic some months previously Continuous drainage was maintained for twenty-five days, there being urinary leakage on the first second and fourteenth days The first leakage occurred by the catheter becoming clogged with mucus and pus, the result of an alkaline cystitis This cystitis which was quite severe, cleared up after three days Leakage on the fourteenth day was due to the fact that the catheter was not placed well down into the bladder Although the catheter was not removed until the fistula had become quite small, suprapubic drainage persisted until a retention catheter was placed in the urethra some days later During the first ten days after operation, daily bladder irrigations were given

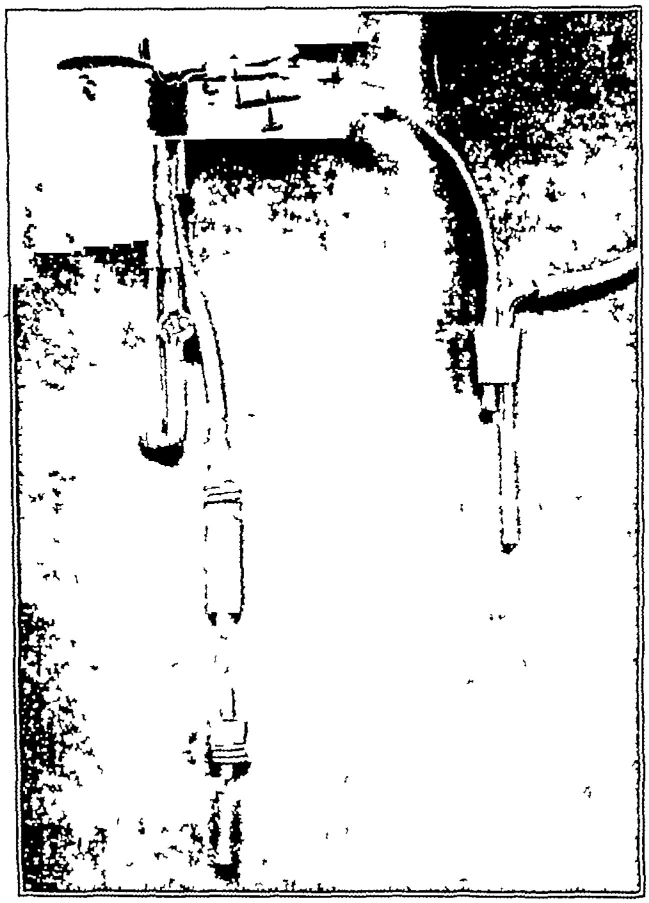

Fig 5—Capillary tube, manometer rubber stoppers and connecting tubing shown without bottles

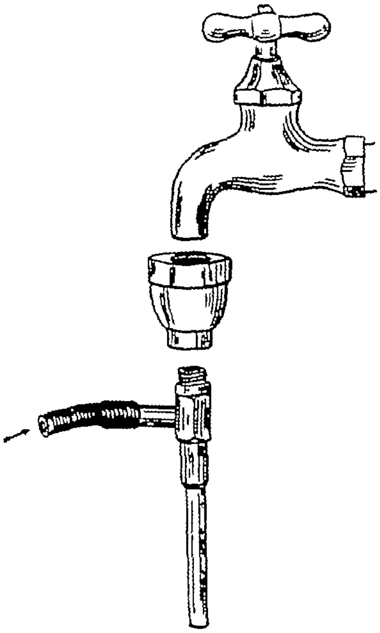

Fig 6—Filter pump and rubber lined coupling for attaching to faucet without screw threads

Case 5—Suprapubic drainage was necessary on account of an impermeable urethral stricture Up to the present, the thirty-ninth day after the operation, the patient has been at all times entirely dry The suprapubic catheter has been changed every fourth or fifth day

Case 6—Through a suprapubic incision, a large pedunculated vesical tumor was excised with the cautery, and on account of the presence of mucus and blood and bits of slough a drainage tube larger than usual was sutured into the bladder A large tube however, does not act well as a siphon For this reason, the suction was connected to a catheter passed into the bladder through the large tube, the latter serving merely as a guide Up to the present the sixth day after the operation there has been no leakage, the catheter having been changed once When this method is used, it is necessary that there should be a water-tight joint where the catheter enters the larger tube This is easily made by the use of a piece of large glass tubing about 5 cm long, one end of which has been drawn out to such a size that it just admits the catheter, and the other end fitting tightly into the end of the large rubber tube Where the catheter enters the glass tube a small cuff of elastic rubber tubing, overlapping both serves to prevent leakage and keeps the catheter from slipping Thus, when it is necessary to remove the catheter it may be easily replaced and retained at any depth in the bladder It is advisable that the large tube be of such a length that this joint may lie in a horizontal position on the abdomen

COMMENT BY DR HUGH H YOUNG

This ingenious apparatus, invented by Dr Davis, has revolutionized the technic of urinary drainage at our clinic, completely transformed the postoperative treatment, changed the condition of the patient from soggy discomfort to cleanly comfort, and produced healthy dry granulating wounds in place of the unhealthy water-logged wounds with adherent urinary salts which we used to see The devices upon which this automatic apparatus depends are as simple as they are clever, the preparation of the vacuum bottle every two days is an easy matter, and the management of the apparatus free from difficulties and complications It is destined to do much for urinary surgery, as well as for other fields requiring constant drainage [29]

THE SUPERNUMERARY URETER

REPORT OF A CASE OF COMPLETE UNILATERAL DUPLICATION

A R SIMON, M D
AND
H O MERTZ, M D
LAPORTE, IND

Reports of supernumerary ureters are becoming more frequent, which very frequency demands records of all such cases, as it emphasizes the possibility of the existence of such an anomaly in every obscure condition of the upper urinary tract While congenital change in a ureter may be associated with corresponding variation in the kidney, the ureteral condition, whether it be an alteration in form,[1] in location,[2] or in number,[3] will not infrequently be the principal factor in the production of a pathologic condition

REPORT OF CASE

History—Mrs T W, Polish, aged 26, with negative previous history, during the forenoon of April 15, 1914, experienced a sudden severe pain in the upper right abdomen relieved somewhat by pressure, with no tendency to radiation and not associated with nausea or vomiting The urine contained macroscopic blood, and a moving renal calculus was suspected, further diagnostic measures at this time however, were refused The patient was again seen, Aug 7 1915, when she came complaining of a marked dysuria with a constant throbbing pain over the bladder region She was having frequent bladder spasms, at which time a few drops of bloody urine would be expelled While the severe abdominal pain had not been repeated, during the past sixteen months she had had periods of bladder irritability Her present attack began four months before, and gradually grew worse, until when seen she was having no rest night or day She had missed the last two menstrual periods

Physical Examination—Palpation elicited tenderness over the bladder region, and vaginal examination, with pressure on the trigon of the bladder, was extremely painful The terminal portion of the right ureter as palpated by the vagina was prominent and sore There was a dull ache over the right kidney posteriorly, and deep fist percussion over this area produced pain The temperature was 99.2, the pulse 100 The blood Wassermann was negative

Catheterized bladder urine, 1½ ounces, contained 0.25 per cent albumin, from five to ten pus cells and from ten to twelve blood cells to the ⅛ objective, with few short strings of streptococci The last few drops of urine, as they flowed from the catheter, were red with fresh blood Catheterization was painful

Cystoscopic Examination—Cystoscopy was performed, Aug 14, 1915, and demonstrated a violently inflamed trigon with flakes of pus and mucus clinging to its raw surface Just to the right of the median line, situated on the posterior margin of the trigon, was a small papilloma Later twice applying the high frequency spark caused it to disappear entirely The left ureteral meatus was normal in contour, but located at an abnormally high position in the bladder On the right side of the bladder at its usual location was the right ureteral orifice, edematous and congested, while downward and inward from this meatus, in the substance of the trigon, was a third opening, almost round, larger than the normal and devoid of the normal liplike folds The inflammatory process centered about this opening There were two small ulcerations located as indicated in Figure 1 The remainder of the bladder was normal

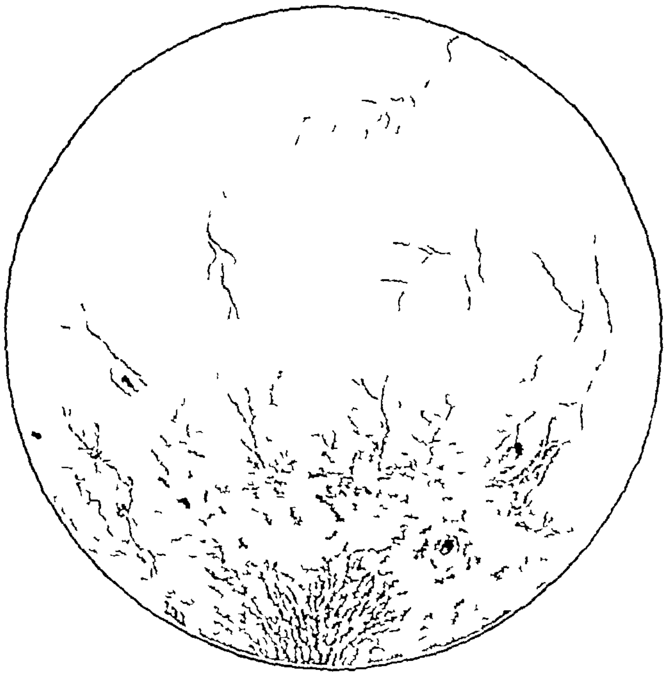

Fig 1 —Cystoscopic findings demonstrating three ureteral meatuses Note the irregularity of the bladder picture and that the inflammatory process completely surrounds the abnormal right opening, it seemingly being more intense in this region

Urine was observed coming from the left and upper right openings in a normal manner, while from the lower right opening it could be detected only at long intervals and then not with normal force At a later examination, Sept 5, 1915, the opening was found entirely covered with mucus It was watched for several minutes, but no urine was seen passing from this opening, but when with the tip of a ureteral catheter the mucus was removed, a larger quantity than had at any time previously been observed coming from it passed into the bladder During ureteral micturition this opening did not advance into the cystoscopic field as does the normal and it remained open when passive The relative sizes of the three openings are accurately recorded in Figure 1

Urine from the left kidney contained 2 6 per cent urea Phenolsulphonephthalein appeared from this kidney in three minutes assuming a deep color in four minutes Urine collected from the upper right opening contained an occasional short string of streptococci Urea was 2 5 per cent, and phenolsulphonephthalein appeared in four minutes, assuming a deep color in seven minutes Urine collected from the lower right opening showed an occasional pus cell, many strings of streptococci, urea only 0.3 per cent, and phenolsulphonephthalein appeared in fifteen minutes in traces only The quantity of urine secreted was only one-third that collected through each of the other two catheters in the same length of time Examinations for tubercle bacilli were negative

Thorium nitrate was injected, and pyelograms were made of the right kidney (Fig 2) Both kidneys were well up in place The two pelves of the right kidney were completely separated, and the ureter from the rudimentary cephalic pelvis entered the bladder at the caudal opening This ureter was the larger The exact relative position of the two ureters in their course varied, as determined by roentgenograms taken at few minute intervals, the ureter from the lowermost pelvis being more mobile Just before the ureters entered the bladder they crossed, the ureter leading to the lowermost, supernumerary bladder opening passing posteriorly, a relation constant in all our roentgenograms

In this review of our case, we wish to emphasize (1) The frequency of the supernumerary ureter, (2) the surgical significance the anomaly may assume, and (3) the possibility of its recognition as a factor in the production of a pathologic condition early in the process

THE FREQUENCY OF URETERAL DUPLICATION

Complete bilateral duplication of the ureters is rare Levison,[4] in reviewing the subject in 1907, found only nine cases Braasch[5] has observed only one case The condition has been reported by Huntington,[6] Pawlow,[7] Wertheim,[8] Lydston,[9] Rumpel,[10] Kelly,[11] and others A complete study of the anomaly was made by Brown, Englebach and Carmen[12] in reporting their case

Complete unilateral duplication is more frequent Motzfeldt[13] found twenty-three double ureters in 4,500 necropsies Huntington,[14] in 5,000 dissections, is reported as having found only five cases of ureteral doubling Wertheim,[8] in 500 operations for carcinoma of the uterus, records only six cases of complete unilateral duplication In the clinical case demanding urologic investigation, the frequency is more marked Pawlow[7] observed three cases and reports six others Braasch, in 1912, reported seven cases of unilateral complete division of the ureter, and Weigert[15] saw seven cases in one year

Huntington concludes from his dissections that the most common ureteral anomaly is a double pelvis and ureter, with the ureters uniting before entering the bladder Cases of single pelvis with the ureter dividing above its insertion into the bladder have been reported Ransohoff[16] states that a duplication of half of a ureter is present in 1 per cent of all subjects

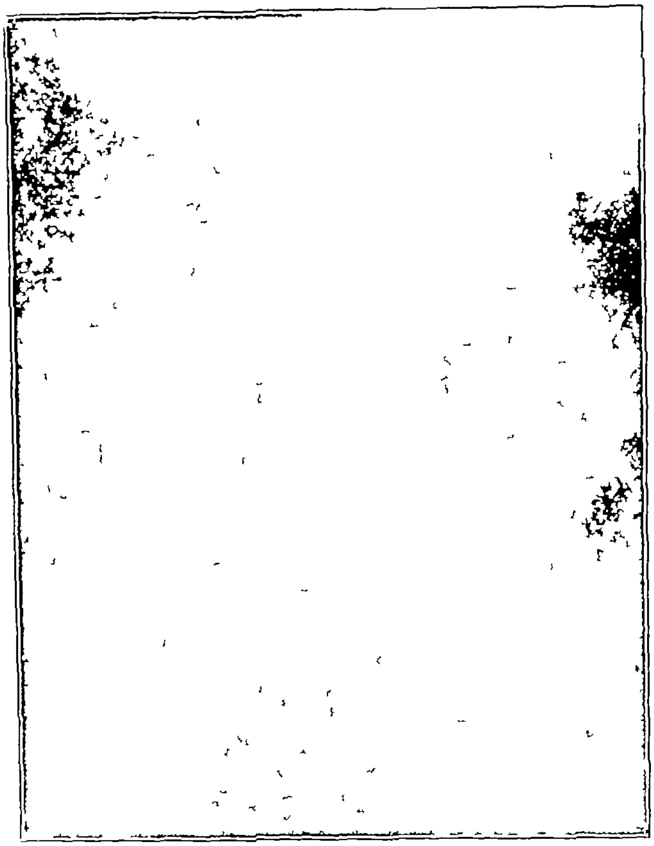

Fig 2 —Complete duplication of the right ureter and pelvis as determined by ureteropyelography A leaded catheter was inserted into the left ureter and 2 c c of thorium nitrate were introduced that we might not fail to locate exactly the position of the left kidney

THE SURGICAL SIGNIFICANCE OF THE SUPERNUMERARY URETER

Not infrequently ureteral anomalies, the surgical significance of which depends on the predisposition their very presence exerts on the development of hydronephrosis and infection, are associated with prenatal renal formations[17] which persist throughout life, rendering resistance to such changes below normal The possibility of the existence of this congenital alteration of the kidney lends an added clinical importance to every case of supernumerary ureter The surgical interest in a supernumerary ureter, however, is very much governed by the location of its meatus Should the opening be extravesical, its correction is possible only by surgical intervention When intravesical its relative position in the bladder will influence its surgical importance When located in the trigon near the vesical neck the folds of the mucous membrane act as valves, closing the opening and resulting in hydronephrosis[10] Should it be near the normal site of the ureteral meatus, this difficulty is not encountered, but if the opening be abnormally small, a condition which usually prevails, stasis is inevitable and infection is prone to occur If the opening is of normal size and has its normal sphincterlike action, the condition can remain latent throughout life, and if discovered will be of no clinical interest, but when there are no liplike folds about the opening, and it remains open when passive, although of normal size, the condition becomes a potential one for harm Draper and Braasch[18] assert that this "mechanical action of the valve can be dispensed with" if the "glomerulotubular pressure is maintained at normal"

In our case there was an absence of the sphincterlike action, the meatus did not grasp the introduced catheter as does the normal meatus, the orifice remained open at all times, it was the largest of the three meatuses, and we considered that the glomerulotubular pressure was lessened, as we felt justified in believing that merely sealing the meatus by mucus was sufficient to obstruct the flow of urine completely The physiologic action[19] of the meatus being absent, and the force of the urinary efflux into the bladder being below normal, conditions were ideal for regurgitation and infection from below, should such be possible

As indicated, there was a wide variation in the character of the urine from the two ureters of the right kidney

Certain writers[7] have suggested the possibility of the development of a constriction of one ureter at the point at which the two ureters cross, thus producing stasis, it usually being the ureter draining the cephalic pelvis most affected In our case, because of the freely movable condition of the one ureter, such a complication would seem improbable

In a partial duplication of a ureter, the narrowing of the canal at its point of division, and the change in its projection thus produced, will often lend the condition a surgical importance

THE DETECTION OF THE SUPERNUMERARY URETER PRODUCING SYMPTOMS

The clinical history of a constant incontinence associated with periods of normal urination at once suggests the existence of a supernumerary ureter with an extravesical opening It may be extremely difficult to locate the orifice of a supernumerary aberrant ureter Furniss[20] and Kelly[11] have exhaustively reviewed the various locations of these meatuses and the difficulties encountered in their detection When the opening is intravesical, this symptom does not obtain, and the determination that an existing renal stasis or infection is associated with a ureteral anomaly, by the symptomatology alone, is impossible

Many such anomalies will at once be recognized by cystoscopy, and there is always some irregularity in the bladder picture But should the opening of the third ureter be among the folds of the trigon or vesical neck, chromo-ureteroscopy may be necessary Mucus covering the opening, as in our case, may prove confusing, and add to the difficulties in a diagnosis Should a ureteral division exist above its vesical opening, the anomaly cannot be diagnosed by cystoscopy alone Pawlow records a case of complete duplication of the ureter until the bladder wall was reached when the two ureters joined, having a common bladder opening It is by the combined use of the cystoscope and Roentgen ray that such cases may be detected In every cystoscopically diagnosable ureteral anomaly, the course of the ureters should be determined, by means of the roentgenogram with leaded ureteral catheters inserted, but in cases such as Pawlow[7] and Young[21] report, this may be insufficient and misleading, when pyelography will be necessary Any anatomic or physiologic alteration in the pelvis can thus be determined also That the case of partial ureteral duplication may be identified, the ureteral catheter should be introduced just within the meatus, and the thorium allowed to flow into the ureter Findings at dissection would indicate that many cases of partial duplication are being overlooked by the clinician The Roentgen ray alone, because of the enlarged kidney shadow, may suggest the anomaly, yet an accurate diagnosis cannot thus be made[22] The functional and bacteriologic tests, possible with the separate collection of urine through the catheter, have the same diagnostic value as in other urologic cases

It is most often the ureter draining the cephalic pelvis which has the abnormally placed opening, which is usually lower and nearer the midline, conforming to Weigert's rule Braasch[5] reports by illustration two cases with the ureter draining the cephalic pelvis entering the bladder at the cephalic vesical orifice

With the examination of a case as thus outlined, it is possible to recognize clinically every case of ureteral anomaly, and determine its surgical importance before a terminal pathology is encountered

With all available data in our case, any explanation of the attack of abdominal pain in 1914 must be purely speculative We had a complete duplication of the right ureter, with separation of the two pelves, the cephalic one being rudimentary There was evidence of infection of this supernumerary pelvis, and the function of this portion of the kidney was poor With the progress of pregnancy, postural treatments and the employment of urinary antiseptics, the bladder symptoms disappeared The dull ache remained over the right lumbar region, and cystoscopy demonstrated, Dec 20, 1915, the third opening still inflamed, with an existing edema of the subjacent mucosa The remainder of the bladder was normal

There was no special diagnostic significance in the presence of the papilloma

CONCLUSIONS

1 Supernumerary ureters are more common than generally appreciated by the clinician

2 They may be productive of a pathologic condition demanding surgical correction

3 An otherwise benign condition may be rendered malignant through the association with a supernumerary ureter

4 Their recognition is possible in every case

5 In our case, the unilateral duplication had a direct bearing on the progress of the pathologic process

THE TREATMENT OF GONORRHEAL FOLLICULITIS BY CAUTERIZATION WITH THE D'ARSONVAL CURRENT

EDGAR G BALLENGER, M D
Fellow of the American College of Surgeons
AND
OMAR F ELDER, M D
ATLANTA, GA

In July, 1915, Swinburne[1] directed attention to fulguration in the treatment of gonorrheal folliculitis Since October, 1915, we have employed the method suggested by him and desire to record the unusually satisfactory results obtained by this treatment in recurrent and chronic gonorrhea

For many years we have understood the part played by the glands of Littre and the crypts of Morgagni in harboring the gonococci where medication could not reach them Knowing this, however, heretofore has been of small importance because there was no definite, dependable remedy to eradicate the organisms or destroy their foci To Swinburne belongs the credit for evolving a method for the destruction of these protected recesses This can be readily and certainly done by inserting an electrode into the follicle and applying the d'Arsonval bipolar current, this is much more satisfactory to deal with than the Oudin monopolar current. Within from two to ten seconds the follicle and tissue immediately around it have become white, and in about one to three weeks it sloughs away, leaving only a smooth granulating surface which finally becomes covered with epithelium and the follicle no longer exists. The patient's immunity, which was able to eradicate the organisms except in protected recesses, now completes the cure if all the recesses have been destroyed and the adnexa are not infected.

SELECTION OF PATIENTS

Naturally acute or subacute conditions should not be treated in this manner. There are many patients who remain free from discharge while under ordinary treatment, but who have a relapse when the injections and irrigations are discontinued or after dissipation or coitus. If the prostate and seminal vesicles are eliminated as possible foci, the chances are about twenty to one that infected follicles keep up the inflammation. This is at times strikingly shown by the disappearance or great reduction in the discharge or shreds within one or two days after the cauterization of inflamed pockets. If the persistent discharge and shreds were not caused by these foci of infection, their disappearance after cauterization of the follicles could hardly have been expected to occur. Of course such a prompt improvement many times does not result, though when it does it proves our contention. At times, especially in subacute recurrences, with immunity lowered, the discharge may be made worse by endoscopy and high frequency. Irrigations and injections of mild remedies may be continued, however, just as if the high frequency treatment had not been administered. This will soon control the recurrence if it should develop.

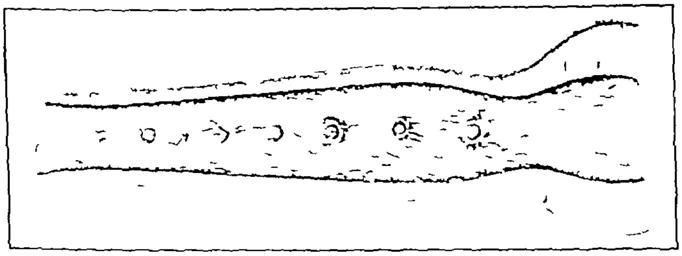

Fig. 1.—Diagrammatic drawing of a segment of the roof of the urethra showing glands of Littre and crypts of Morgagni.

When all the foci have been destroyed, a continuation of mild remedies will then effect a cure without further relapses. It does not seem difficult for Nature to secure immunity to gonococci on a smooth urethral mucosa. Infected follicles provide conditions which are unfavorable for the immunizing processes, especially in chronic infections. This probably accounts for the uncertain results in the treatment of gonorrhea and for the lack of uniformity with vaccine therapy. The average patient is largely immune to gonococci except on mucous and serous surfaces, and even here local immunity can be developed with a fair degree of ease if protected recesses are absent or can be destroyed. In terms of modern warfare, we may say that the organisms may be destroyed without much difficulty by Nature's medical artillery if the infection is not protected in the trenches. The high frequency current is the gonococcal trench destroyer. This becomes readily apparent when an endoscopic examination is made a few weeks after follicles have been cauterized, and at their former sites we find only smooth mucosa. Heretofore chronic and recurrent gonorrhea, even in the hands of experts, did not receive treatment that could be depended on to afford definite results in a very encouraging percentage of cases. We knew the advantage of massage of the prostate, and realized the persistent character of seminal vesiculitis, but many patients who did not have such complications were not infrequently refractory to treatment because of infected follicles. Since Swinburne has suggested to us an effective means of destroying these foci, this former bugbear of medicine can be placed on an accurate scientific basis which will afford results as certain as our judgment is accurate in selecting appropriate cases and directly in proportion to the skill we exercise in detecting and destroying all of the protected recesses. As previously stated, we should not expect this treatment to cure prostatitis and seminal vesiculitis.

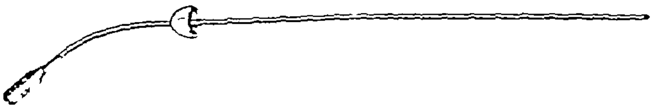

Fig. 2.—Ordinary fulgurating electrode, showing only a small amount of exposed wire beyond the insulation.

Fulguration is of particular value in chronic folliculitis in which there is a beaded condition of the urethral canal, although more frequently recurrent infections result from infected follicles which have not sufficient infiltration to render them palpable.

INSTRUMENTS

The most satisfactory urethroscope both for diagnosis and cauterization is McCarthy's improved cysto-urethroscope. This permits an easy examination and provides a constant flow of cool sterile water. The electrode should be one which may be inserted into the bottom of the follicle and thus cauterize the entire tract. The insulating sheath should extend only beyond the lever for controlling the distal point of the electrode. This kind of an electrode may be made by inserting a silver wire, of about 22 gage, through a urethral catheter. A small bulb may be made on the end of the silver wire by holding it in a Bunsen flame until it melts. Such a bulb on the end of the electrode facilitates its introduction into the depths of the follicle. Some of the early failures were due to the fact that the electrodes used were placed only over the openings of the follicles and not inserted into their depths, as they should have been, for on subsequent examinations the follicles were still present.

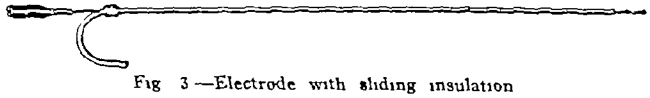

Fig. 3.—Electrode with sliding insulation.

By moving the silver wire up and down through the insulating sheath, the desired amount of exposed electrode may be obtained. The amount of exposure needed, of course, varies with the depth of the follicles to be cauterized. The sheath should be wrapped with adhesive plaster around its proximal end so as to form a bulbous mass to prevent its passing too far into the urethroscope when the wire is advanced. The illustrations show several types of electrodes we have made with silver wire and small rubber tubing A small rubber cap is placed over the electrode to prevent the irrigating solution from spraying on the surgeon's face A rubber band rather tightly applied around the penis just back of the corona will cause good dilation of the urethra without unnecessary wastage of irrigating solution Each follicle is cauterized until it becomes distinctly white

REPETITION OF CAUTERIZATION

The treatment with the high frequency current may be repeated in from two to three weeks, as indicated by the reactions and by persisting manifestations of infected follicles Inflammation of the prostate and seminal vesicles should receive appropriate treatment during this time

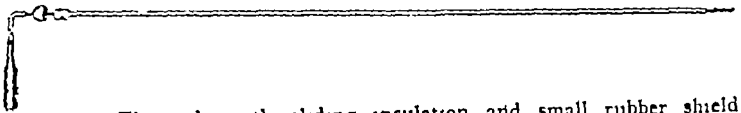

Fig 4 —Electrode with sliding insulation and small rubber shield to prevent the squirting of irrigating solution into the examiner's eye

The following case histories have been selected from fifty-four patients treated with the high frequency current for persisting or recurrent urethritis Some had been treated for as long as six years by a number of physicians and specialists, but the discharge and urethral shreds still continued Two or three treatments were the average required after we learned the importance of inserting the electrode to the bottom of the pocket and to apply the current until the mucosa overlying it turned white A number of the patients returned to their homes and allowed their physicians to continue mild irrigations During the two or three weeks' interval it was most gratifying to note the marked improvement in some of these patients who had for years been unsuccessfully treated by the usual measures Without burdening the reader with the details of many of the histories, we should like merely to say that, in suitable cases, we have never been able to secure such definite and prompt results by any measure or remedy hitherto advised for this class of patients

REPORTS OF CASES

Case 1 —Mr A, with gonorrhea of four months' duration, thought himself cured, and married without examination to determine the absence of gonococci Recurrence developed on the wedding trip before he indulged in coitus with his wife, and he reported for treatment two days later with a slight purulent discharge with many typical intracellular diplococci An examination was made with McCarthy's cysto-urethroscope, and two inflamed glands of Littre were found on the roof of the urethra about 1 inch back of the meatus These were fulgurated until they became white The discharge did not recur after this treatment The urine has since remained clear in spite of alcoholic and sexual excesses

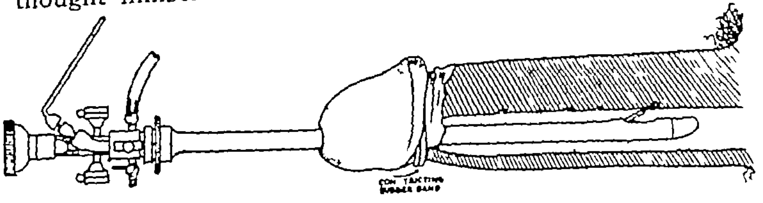

Fig 5 —Sagittal section of penis with McCarthy's water dilating cysto urethroscope in position, with electrode inserted into a gland of Littre ready for fulguration

Case 2 —Mr B, with gonorrhea of four months' duration, thought himself cured three times, but on discontinuation of treatment the discharge would recur Fulguration of six glands of Littre and one lacuna of morgagn in the roof of the urethra caused an increase in the discharge and shreds in the urine for four days Mild irrigations of potassium permanganate soon cleared the urine of pus and shreds There has been no further recurrence

Case 3 —Mr C had had gonorrhea three years ago, but a discharge had been seen more or less constantly in the mornings during this time, and the urine always showed mucous and pus shreds, though no gonococci could be found in the discharge The prostate and seminal vesicles were normal Endoscopy showed five distinctly inflamed glands of Littre These were cauterized with the high frequency current, but the discharge continued though in a smaller quantity for three weeks, when another fulguration treatment was given to two follicles which had been incompletely destroyed Within two weeks the discharge ceased, the urine became clear, and no further relapse has occurred

Case 4 —Mr D had gonorrhea six years ago, and had never been free from discharge since Eight beadlike masses varying in size from a shot to a bean could be palpated along the urethra These were treated by fulguration, there was a prompt reduction in the size of the lumps, though the discharge continued In eighteen days another treatment was given with the high frequency current, and five inflamed indurated follicles were cauterized While the condition was improved, there could still be felt two nodules at the end of three weeks when these were deeply cauterized The urine is now nearly clear, and the morning discharge no longer appears

THE DURATION OF THE NURSING PERIOD IN WOMEN OF THE UNITED STATES

A GRAEME MITCHELL, M D
Clinical Assistant, Children's Hospital, Philadelphia
PHILADELPHIA

It is of interest to know the present average length of breast feeding and to determine any change which has occurred in recent years

Such a study is more readily undertaken because of the paucity of statistics on the subject in this country, and because of the difference of opinion which prevails regarding the increase or the decline of nursing ability in American women This difference of opinion is well illustrated by comparison of the statements of two eminent authorities Holt[1] says "In spite of all effort to the contrary, it is nevertheless a fact that the capacity for maternal nursing is steadily diminishing in this country" On the other hand, Griffith[2] says "The ability to nurse is no longer materially diminishing, provided the woman has been raised and continues under healthy normal conditions These conditions are improving in the upper classes and are not changing for the worse in the poorer" Dr Griffith's statement applies, not only to this country, but to civilized nations in general

It is needless to call attention to the vast importance of such a subject One realizes the great advantage of maternal over artificial feeding, but it is brought home very forcibly by statistics, such as those of Davis,[3] which show that above the age of two weeks the proportion of deaths in bottle-fed babies is six times that of breast-fed babies

---

[1] Holt, L E Infancy and Childhood, D Appleton & Co, New York and London, Ed 4 1908, p 168

[2] Griffith, J P C The Ability of Mothers to Nurse Their Children, The Journal A M A, Nov 23, 1912, p 1874

[3] Davis, W H Am Jour Pub Health, 1912, ii, 67

Our task in this matter is clear Many times breast feeding is unnecessarily stopped Most authors agree that in such instances the ignorance of the laity plays an important role, but that this is perhaps secondary to the lack of perseverence of the physician Martin,[4] working in the Midwife School of Stuttgart, found that from 1884 to 1903, of 10,000 mothers, 88 2 per cent nursed, 10 5 per cent partly nursed, and 1 3 per cent did not nurse at all Later they were able to make all the mothers nurse Thorn,[5] quoting Oppenheimer of Munich, says "Of 1,000 mothers, 642 did not nurse, of whom only 31 had valid reason for not performing their maternal duty" Thorn believes that with encouragement, care and proper feeding, 90 per cent of all mothers are able to nurse

In our own studies it will be seen that about 20 per cent of American mothers of a certain class never suckle their offspring One cannot resist the temptation here to plead for a lessening of this number Education of the laity to the advantage of breast feeding and the danger of bottle feeding, proper care of the breast during and after pregnancy, and regulation of the mother's health, habits and diet should help us to encourage and prolong lactation

Many of the German statistics are taken from maternity hospitals Absolutely accurate statistics are available practically only in such institutions, but patients are discharged from them usually at the expiration of ten days or two weeks The problem obviously does not lie here, although it is important to remember that the foundation for successful breast feeding is often determined in this interval It is at this time that the obstetrician might work in conjunction with the pediatrist with profit, and perhaps with some reduction in infant mortality

Pistor[6] in 1894 collected 12,809 cases from the midwife tables in Freiburg, in 24 per cent of which the mothers did not suckle at all Wiedow[6] in 1895 recorded that of 525 women from the Frauenklinik at Freiburg, only one half could suckle after the first two weeks Keller[7] found that about 30 per cent of children were exclusively artificially fed In Hohlfeld's[8] statistics on 5,023 nursing women, 27 5 per cent continued to nurse over six months, and Weiss[9] in his studies on 1,622 cases reported that 25 per cent nursed longer than this period Bluhm,[10] from a review of German literature, concluded that a third of German women nursed sufficiently, somewhat more than a third were physically unable to nurse, and less than a third nursed insufficiently or not at all, from deficiency of intelligence and desire, or because of social conditions

In England, Blacker[11] found that of 1,000 cases taken from the poor, only 2 4 per cent never suckled, while 74 7 per cent suckled their children seven months or longer Fordyce,[12] in 374 deliveries of 100 mothers, stated that 69 per cent of the babies were nursed on the breast wholly or partly for at least two months, the average being ten months, and that the average period of lactation was as long in later as in earlier infants

In this country some of the statistics are of interest Dr Eleanor Jones[13] quotes the studies of Schwartz of 1,500 women, of whom 96 per cent nursed one month or less, 88 per cent three months and 77 per cent six months The result of a questionnaire sent by Sedgewick to married physicians in the United States is also mentioned It reveals that 80 per cent of wives of American physicians succeed in nursing one or more children three months or longer

Koplik[14] found of 1,007 infants, seen in private practice, 56 per cent were breast-fed, and of these, only 40 per cent longer than four months According to Snyder,[15] a study of 1,000 mothers is contained in a recent pediatric work Five hundred were poor and living in tenements, and 90 per cent of these mothers nursed nine months The other 500 mothers were prosperous and lived in healthy surroundings, but only 17 per cent nursed nine months

The value of statistics such as these depends on the number of cases, the memory and intelligence of the mother or person giving the history, and the accuracy with which the history is taken

It is the object of this communication to present an analysis of almost 3,000 cases taken from the records of the Children's Hospital during the last fifteen years As it was the desire to determine as far as possible the ability of the mother to nurse, many cases were excluded It was the duration of the physiologic period of lactation, apart from disease or deliberate act of the mother, which was the problem to be solved Thus, when the records showed that the mother stopped nursing from some such cause as going to work, or lactation was terminated by an acute infection, or mammary abscess, the case was not included

It may certainly be stated, however, that the statistics to be presented show with reasonable accuracy the length of breast feeding in the hospital class of Philadelphia women These women are of different nationalities, including Italian, German, Russian, Irish, Armenian and others Many of them are native-born Americans, and a fairly large percentage consist of Jewish and colored women They therefore should represent the same classes which are found in most of the large American cities, at least along the eastern seaboard

It must also be remembered that many babies admitted to the hospital in the summer are suffering from gastro-enteritis or gastric and intestinal disturbance of some type It is not to be denied that this condition is much more frequent in bottle-fed babies, and that the bottle-fed baby is more liable to acute infections and illness of any nature than the breast-fed baby Reasoning from this, we must come to the conclusion that the average length of breast feeding in babies admitted to the hospital is less than for babies of the same class not admitted to the hospital This statement is made advisedly Consultation with social workers in Philadelphia shows that they seldom encounter mothers who never nurse their children

One must understand that in getting a history of breast feeding the baby has not necessarily been wholly breast fed during the entire period stated, but has been receiving most of its nourishment in this way

From the beginning of 1900 to the end of 1904 there were 734 cases in which the average length of lactation was 5 92 months From the beginning of 1905 to the end of 1909 there were 827 cases with an average of 6 36 months From the beginning of 1910 to the end of 1914 there were 1,258 cases with an average of 5 76 months Therefore, of a total of 2,819 cases during the fifteen years, the average length of lactation was 6 months [10]

Table 1 shows a study of the statements of 2,819 mothers when questioned regarding the length of time their children were breast fed It is seen that there has been no appreciable decline in the length of maternal nursing in the last fifteen years The rather higher percentage of cases at from 11 to 12 months, from 17 to 18 months and from 23 to 24 months is caused by the fact that here the mothers' statements that "baby nursed a year," "baby nursed a year and a half," and "baby nursed two years," are included

27 36	12 or longer	38	Nursed over 24

* One week

If it is borne in mind that we are studying the statements of the poorer class of city women, we may be justified in drawing the following conclusions

1 There has been no decline in breast feeding in the last fifteen years

2 The women of the poorer class compare favorably in the period of lactation with the women of the more prosperous class in this country

3 The women of this country compare favorably in the period of lactation with European women

4 The average period of lactation in children entered at the hospital was six months

5 Twenty per cent of the women did not nurse their children, 80 per cent nursed one week or longer, 55 per cent nursed three months or longer, 42 per cent nursed six months or longer, 34 per cent nursed nine months or longer, 27 per cent nursed a year or longer, 9 per cent nursed eighteen months or longer, and 2 per cent nursed two years

6 For the reason previously pointed out, namely, the greater susceptibility of artificially fed babies to gastro-intestinal and nutritional disturbance, the infants brought to the hospital were, in the large majority of cases, bottle fed at the time of their entrance there The conclusion is inevitable that the figures given represent the minimum of lactation

1805 Pine Street

---

16 In presenting these statistics, I realize they are open to criticism because they include the extremes The average includes all cases

---

THE ETIOLOGY OF TYPHUS FEVER IN MEXICO (TABARDILLO)

PRELIMINARY COMMUNICATION *

PETER K OLITSKY, M D,
BERNARD S DENZER, M D
AND
CARLOS E HUSK, M D
NEW YORK

The work covered by this report was begun in February, 1916, in Matehuala, Mexico, and was interrupted in the early part of March because of the necessity of Americans leaving that country Studies were made of the blood of typhus fever patients to determine whether an organism could be recovered, and, if so, whether it conformed with the organism described by Plotz, Olitsky and Baehr[1] in the blood of endemic typhus fever patients in New York and in cases of typhus fever in Serbian immigrants quarantined in New York harbor The blood of the patients when injected into guinea-pigs gave the characteristic typhus reaction The first three blood cultures were made in a medium containing 0 5 per cent glucose, and an organism was recovered in one case Cultures were made in twenty-eight cases with a 2 per cent glucose medium, which is the sugar concentration used in the earlier work in New York Of the latter cultures only eight could be observed a sufficiently long time, and in all of them the same organism was found

The organism is an obligate anaerobic gram-positive bacillus which in morphology and cultural characteristics, including acid production in various carbohydrates, is identical with the *Bacillus typhi-exanthematici* The injection into a guinea-pig of a colony taken directly from the blood culture tube proved the organism to be pathogenic Agglutination tests performed with serums taken in different stages of the disease showed negative results during the early part of the illness, an occasional positive reaction at or near the crisis, and uniformly positive results after the crisis

---

* From the Pathological Laboratory, Mount Sinai Hospital

* March 20, 1916, shortly after the departure from Mexico, Dr Husk succumbed to an attack of typhus fever contracted in the prosecution of this work.

* This work was carried out with the aid of a donation made by a number of the directors of the Mount Sinai Hospital and the George Blumenthal, Jr, Fellowship in Pathology We wish to express our indebtedness to the officials of the American Smelting and Refining Company, whose cooperation enabled us to undertake the work

1 Plotz, Olitsky and Baehr Jour Infect Dis, 1915, xvii, 1

In cultures made from lice taken from the clothing of typhus fever patients, the same organism was obtained The injection of lice into guinea-pigs produced a febrile reaction, and at necropsy the characteristic splenic lesion was found In cultures from the spleen, an organism was recovered showing the morphologic characteristics of the *Bacillus typhi-exanthematici*, but on account of the sudden termination of the work, the organism could not be further studied

ELECTIVE LOCALIZATION IN THE BRONCHIAL MUSCULATURE OF STREPTOCOCCI

FROM THE SPUTUM OF CASES OF BRONCHIAL ASTHMA PRELIMINARY REPORT

SVERRE OFTEDAL, M D
FARGO, N D

According to the work of recent investigators and observations of clinicians, it has become evident that the phenomena observed in an attack of bronchial asthma are fundamentally due to a tonic spasm of the bronchial musculature Just what is the cause of the spasm is still a matter of conjecture Recently Koessler[1] has reported the finding of a fusiform anaerobic bacillus in the sputum of asthmatic patients which he regards as possibly specific, the evidence being mainly its presence in a large number of cases He also reports the success of vaccine treatment, which has been especially marked in the cases in which this organism was present in the sputum The sputum in these cases has, however, contained certain other organisms, notably the pneumococcus, *Streptococcus hemolyticus* and *Streptococcus viridans* As further evidence of the bacterial origin of the disease is the presence in a large percentage of the cases of associated lesions, particularly of the nasal passages, which strongly suggests a primary focus of infection The removal of such a focus has often caused a marked improvement in the condition of the patient

The foregoing evidence suggested to me the possibility of the reproduction of the disease in lower animals by the intravenous injection of cultures of the sputum of asthmatic patients The reproduction of Rosenow has shown repeatedly, and in a great variety of pathologic conditions, that bacteria (streptococci) display an elective affinity for certain tissues In our work on herpes zoster[2] we have shown that streptococci isolated from the tonsils, the pyorrheal pockets, the spinal fluid and the sputum of cases of herpes zoster have an elective affinity for the posterior root ganglia The technic employed in these experiments was essentially the same as that used in the experimental work cited above

The three cases thus studied were selected to represent different types and stages of the disease In the first case, a man, aged 39, has had asthma of a particularly severe type for seventeen years, and there is also present a marked bronchitis with profuse expectoration The second patient has asthma of rather short duration (three years), and the lung changes, except during the active stage of the disease, are comparatively slight The third case is of twelve years' standing, but is of the remittent type, and the sputum was collected during the latent stage As an illustration of a case history, that of Case 1 is given in more detail

Case 1—H B, man, aged 39, referred to me in January, had had asthma since he was 22 Prior to that time, since the age of 14, he had coughing spells every night He had croup during the first year of life, when 11 years of age he was taken to a doctor to be treated for "catarrh in the head" The attacks of asthma came on very suddenly, the patient remembers distinctly the first night when he had an attack. After that he had an attack some time during each twenty-four hours, usually after the evening meal, but the time of attack varied, showing a marked tendency to continue at the same time of the day for periods of two weeks or more This condition continued for many years At one time the patient sought relief by change of climate, going to northern Texas, which brought temporary relief, but after one month in that locality he says he was just as bad as ever The attacks have never seemed to be influenced as regards onset by any external factor, psychic or otherwise His father's father and two of his father's sisters had asthma, two sisters had had attacks of croup during childhood, and one brother died of tuberculosis at an early age

At the time the patient came to my office he was suffering from frequent and severe attacks of asthma, and also had a marked bronchitis with profuse expectoration The temperature ranged between 99 and 101 5 There was no active lesion to be found in the nasal passages, but the inferior and middle turbinates had been removed several years before. Over both lungs were sibilant and sonorous râles, of the vague character commonly present in advanced cases of bronchial asthma The cardiac and hepatic dulness were almost obliterated by the resonance of the distended lungs There were no cardiac murmurs, and beyond these chest findings the examination was practically negative Cultures were made from the carefully washed sputum and a vaccine prepared directly from the ascites-dextrose-broth culture After the first dose of vaccine the patient had a violent reaction with chills and marked rise of temperature Since the beginning of the vaccine treatment he says "he has never had an attack of asthma" The bronchitis has persisted, however, although to a less degree, up to the present time

No attempt was made to isolate any particular type of organism Great pains were taken, by gargling and repeated washing of the sputum in sterile salt solution, to avoid mouth contamination, cultures being then made in ascites-dextrose-bouillon, and the twenty-four hour culture centrifuged and injected in varying amounts intravenously

Of the twenty-one animals injected, all except three have shown typical lung lesions In the three exceptions, the animals injected with the same strain from a twenty-four hour culture of lung tissue died a few hours later with an overwhelming septicemia All of the other animals lived until chloroformed, which time varied from forty-eight hours to two weeks after injection After the first twenty-four hours after injection most of the animals seemed to feel fairly well and would take nourishment A distinct difference was invariably observed, however, in the manner of breathing, the respirations being markedly reduced in rate as compared with control animals, and intensely labored. Squeaking râles could be heard with the stethoscope, and in one of the rabbits there was an audible wheezing during expiration Several of the animals would at times hold the head high in the air as if suffering from air hunger At necropsy the lungs were found to be greatly distended, filling the chest cavity They were in most of the animals of a dull grayish color, at times mottled brownish plaques In some, however, in which large doses had been injected, the lungs were distinctly hemorrhagic and showed considerable infiltration, mingled with the emphysematous areas, in microscopic section The grayish looking lungs were extremely light in weight, the smallest particles floating in water Pressure elicited distinct crepitation, and all other signs of emphysema were present On microscopic examination the main changes in these lungs were found to be A marked distention of the alveoli, and a thinning and often rupture of the alveolar walls The blood vessels were engorged and there was considerable perivascular round cell infiltration A very marked change was seen in the bronchioles These were contracted as if in spasm, and the mucosa was thrown into folds which almost completely obliterated the lumen In the peribronchial tissue there were small areas of hemorrhage and marked round cell infiltration In the substance of the musculature a considerable number of streptococci were found, usually lying between the muscle fibers and toward the inner margin of the muscle wall In this connection may be mentioned an interesting observation in the animals injected from the sputum in Case 3 Here the sputum culture was largely composed of a short, plump, polar-staining bacillus, and very few streptococci were present But tissue cultures of the lungs made forty-eight hours after injection showed a pure culture of streptococci, while stains of the lung tissue showed streptococci present in the musculature, just as in the animals injected with cultures from Cases 1 and 2, in which almost pure cultures of streptococci were present

[1] Koessler K K and Moody A M Etiology of Chronic Bronchitis with Special Consideration of Those Forms Associated with Bronchial Asthma abstr, The Journal A M A March 27 1915 p 1104

[2] Rosenow E C and Oftedal Sverre The Etiology and Experimental Production of Herpes Zoster Jour Infect. Dis 1916 xviii, 477

Cultures were made of the blood and other body fluids, and also of several of the other organs besides the lungs in order to disprove the possibility of a generalized bacteremia In nearly every case the blood and all organs except the lungs were found to be sterile, while the lungs yielded a pure culture of streptococcus One rabbit was kept for two weeks, being injected every two days with twenty-four hour cultures from the sputum in Case 1 Here the lungs were found to be markedly emphysematous, while some areas, especially around the larger vessels and bronchi, showed a marked tendency to atelectatic compression Cultures from the lung tissue showed *Streptococcus viridans*

As regards the morphology of the organisms, both the hemolyzing and green-producing streptococci were found, while in one case a pure culture of *Streptococcus mucosus* was obtained from the lung tissue

The amount of hemorrhagic infiltration associated with the emphysema in these cases seemed to depend largely on the dosage of the organisms injected Thus it was found that by injecting the growth from 1 ounce of a twenty-four hour culture of the sputum in Case 1 the typical and almost uncomplicated condition of emphysema could be produced repeatedly

From an analysis of these findings, associated with a systematically studied history and examination of a considerable number of cases, it seems evident that the sputum of at least a large number of persons suffering from bronchial asthma contains organisms (streptococci) which have an elective affinity for the bronchial musculature and that the invasion of the lungs by these organisms, when made possible by any factor, psychic or otherwise, which tends to lower the resistance of the individual, will bring about a tonic spasm of the muscles of the bronchioles and cause the typical phenomena so commonly observed clinically in patients suffering with an attack of asthma In other words, these experiments illustrate another example of elective localization of streptococci There are no doubt a number of factors which must be taken into consideration I would particularly emphasize a hereditary predisposition to weakness of the respiratory tract In nearly all of the cases studied there is a family history of asthma or other respiratory tract disease Many of the cases give a history of spasmodic laryngitis (catarrhal croup) during childhood, which strongly suggests a congenital lack of resistance, manifesting itself as bronchial asthma later in life with the development of a focal infection, or a weakening disease of the lungs, such as an attack of acute bronchitis

MERCURIC CYANID POISONING WITH RECOVERY *

A O GETTLER, PH D
Pathologic Chemist, Bellevue Hospital, Assistant Professor of Chemistry, University and Bellevue Hospital Medical College
AND
WILLIS BAKER, M D
Assistant Pathologist, Bellevue Hospital
NEW YORK

Poisoning by mercuric cyanid is a rare occurrence The case here reported is of interest because of the hopeless prognosis, subsequently followed by complete recovery, and the unusual opportunities at hand for making chemical and physical analyses of blood and excreta for a period of a month and a half

History—A German girl, aged 20, attempted suicide on the afternoon of Aug 1, 1915, by entering the cabinet of the physician by whom she was employed as domestic, and taking therefrom one tablet from a bottle marked "Gift" Subsequently this was proved to be mercuric cyanid in 0 5 gm (7½ grain) tablets She was not found until several hours later, and then promptly brought to the hospital by an ambulance

Clinical Course—On admission to the hospital she was in a state of partial collapse, she responded well to stimulation, and was lavaged with a copious amount of potassium permanganate (1 1,000 solution), the vomiting and nausea continuing We are not certain of the immediate action of the poison, as it was quite impossible, on admission, to get from her any description of the early symptoms On several occasions later she said that as far as she knew, she had suffered no convulsions or loss of consciousness, but remembers only vomiting violently from the very first

Twenty-four hours after ingestion of the poison, the patient had a general convulsion, vomiting continued and bowels were loose, the urine was "q s"

On the third day a rash was present over the face and arms, no urine was observed on this day, but may have been voided with the stools, which were very loose and frequent

On the fourth day the mouth was sore The patient was salivated She was drowsy and stupid Vomiting continued No urine was passed for twenty-four hours, a catheterized specimen was less than half an ounce

On the fifth day the breath was fetid, the tongue swollen, the gums ulcerated The patient was in coma most of the time There was incontinence of feces Phenolsulphonephthalein was injected, but no urine was recovered at the end of the first and second hours by catheter

---

* From the Department of Pathology, Bellevue and Allied Hospitals, Dr Charles Norris, director

On the sixth day phlebotomy was done, 15 ounces being withdrawn On this day the patient passed 2 ounces of urine after fifty hours' complete retention The vomitus was green The patient complained of headache

On the seventh day the patient was menstruating The bowels were very loose, and there were abdominal pain and tenderness

From the eighth to the twelfth days the urine increased in quantity daily and was now 15 ounces Vomiting was persistent

From the thirteenth to the nineteenth days the vomitus was bloody The urine amounted to about 24 ounces daily

On the twenty-third day the vomiting had stopped The phenolsulphonephthalein test revealed 12 per cent in two hours

On the twenty-ninth day the appetite was improving

On the thirty-first day the patient was out of bed for half an hour She was given a soft solid diet She had lost 20 pounds

On the thirty-eighth day she was about the ward most of the time, and was very cheerful

On the forty-fifth day she was well, and was discharged to court for trial

Throughout her stay in the hospital, pulse, respiration and temperature ranged within normal limits, except during the temporary periods of coma, convulsions, etc

‡ Method of Lewis and Benedict (Jour Biol Chem, 1915 xx 61)
§ Zeiss immersion refractometer $\Delta Nd \times 10^3$
¶ Milligrams per hundred cubic centimeters of blood

Urinalysis—Blood and albumin were present in the urine for the first fifteen days From then on there was no blood, and albumin was present in decreasing amounts On the day of discharge only a very faint trace was present

Treatment—Gastric lavage was performed on admission and the first day thereafter The bowels were kept open by small doses of magnesium sulphate given in water at frequent intervals Hot packs and high hot colon irrigations were administered regularly to aid elimination and as a general tonic Cerium oxalate 2½ grains was given every four hours, but failed to control the vomiting, which persisted, notwithstanding for twenty-three days Nutritive enemas (eggs, milk and sugar) were resorted to when the vomiting was particularly severe The patient was on a milk diet the first thirty days, and fluids were forced in the form of lemonade, cracked ice and water The stomatitis was relieved by frequent gargling with potassium chlorate solution

Toxicologic Findings—The vomitus, stomach washings urine and feces of the twenty-four hours after admission were analyzed for poison In the combined lavage and vomitus, both the mercury and the cyanid were easily detected The urine and the feces showed the presence of mercury, but no cyanid, the latter evidently being destroyed *in passing through the organism* Analysis of the feces on the sixth day showed mercury present in traces only The blood which was removed on this day (450 c c) was also analyzed for poison Before starting on this venture, we knew that if any were present, it must be an extremely minute quantity, and therefore from the beginning the greatest care was applied in its detection The most delicate method possible was used[1], the blood was decomposed and brought into solution in the usual way by the use of previously tested mercury free reagents, potassium chlorate and hydrochloric acid The mercury was then deposited on a thin strip of gold by means of the electric current, carefully washed, dried and placed in a glass tube previously drawn out to a capillary at one end, the hydrogen generator being attached to the other end After pure hydrogen had been passed through very slowly for half an hour, the tube containing the gold foil was carefully heated, volatizing the mercury, which was then carried along in the slow stream of hydrogen and deposited on the cold drawn out end of the tube With a strong lens, a few microscopic globules of metallic mercury were visible, which with iodin gave the red iodid of mercury reaction

The combined feces, urine and vomitus of the sixteenth day were analyzed and found to contain no mercury

Spectroscopic examination of the blood on the first day revealed no evidence of cyanhemoglobin

COMMENT

Anuria began on the third day and lasted two days, the patient then being in typical uremic coma and presenting the characteristic picture of severe mercurial nephritis The prognosis was extremely grave and a fatal termination was to be expected, from experience in poisoning with mercuric chlorid, in which recovery is extremely rare after onset of profound uremic coma and anuria

Blood Findings—The nonprotein nitrogen of the blood increased steadily with the urinary retention The surprisingly high figure of 292 mg per hundred c c of blood (the normal is from 35 to 45) was obtained Although higher figures have been reported in the blood, this observation is of interest because of the subsequent recovery after so severe a degree of retention In our previous experience all cases which presented values of 200 mg or above terminated fatally

The cryoscopic figures are noteworthy From the normal average of —0 560 C the depression of the freezing point was gradual as the blood retention increased From the tenth day on, when the urinary excretion was increasing daily, the freezing point determinations were found to decrease steadily, the greatest depression being noted twenty-one days thereafter, namely, —0 772 on the thirty-first day This would appear to us to indicate that the kidneys in resuming their function regained their water excretory power more rapidly than that of the crystalloids, retention of which caused the very low freezing point

Chemical—The toxic action of mercuric chlorid on the kidney is due to the positive Hg^{++} ion, while potassium cyanid exerts its extremely rapid lethal properties (acute respiratory death) through its negative CN^- ion Mercuric cyanid, $Hg(CN)_2$, contains both of these, and *a priori* one would expect it to have the combined effect of the two However, its toxic action resembles that of the chlorid and not that of the cyanid salt, as indicated by the clinical course of this case, which resembles strongly that of poisoning with mercuric chlorid (with the possibly notable exception of a single convulsion on the second day) This action of mercuric cyanid may be due either to its small degree of ionization, or to the isometric structure, $Hg(NC)_2$, which has been ascribed to it by some authorities

NOTES ON GRIP EPIDEMIC IN CHICAGO

A M MOODY, M D
AND
J A CAPPS, M D
CHICAGO

The epidemic of grip seems to have spent its force in the months of December and January Only sporadic cases have occurred since then It is highly desirable that the records of this epidemic in various communities should be compiled as completely as possible by all those who have given the subject special study Already valuable reports have come from the New York Department of Health, the Memorial Institute for Infectious Diseases of Chicago, and from the United States Public Health Service The health departments, however, are handicapped by the fact that grip is not generally reported as a contagious disease This places the greater responsibility on individual physicians who have had opportunity to observe many cases In this spirit we desire to publish our data

The frequency of the disease in private practice is not easy to determine without an extensive house to house canvass In the absence of any large statistics, we submit the number of cases occurring in four institutions in which written records were kept of the clinical diagnosis

OCCURRENCE OF CASES

	No Persons	Grip Cases	Percentage Morbidity
Michael Reese	140	27	19
Illinois Training School for Nurses	275	24	9
O'd Men's Home	112	69	61
St Luke s Hospital Nurse s Training School	150	24	16
Total	677	144	21

Nearly all of the 144 grip patients here referred to were unable to report for duty There were many others with colds who remained on duty and were not included in the table

The leukocytes were estimated in fifty-three cases of grip, several counts being made in many of the patients

Thirty cases had a leukocyte count of 10,000 or less Many of these showed a leukopenia

Sixteen cases had a leukocytosis of from 10,000 to 15,000

Seven cases had a leukocytosis of 15,000 or more

From these figures it is seen that leukocytosis is usually absent, although temperature of from 1 to 3 degrees above normal was the rule

In thirty-one cases careful bacteriologic cultures were made on blood agar plates with the following results

Streptococcus hemolyticus occurred thirty-one times

Streptococcus viridans and the pneumococcus occurred thirty-one times

Streptococcus mucosus occurred once

Hemolytic staphylococci occurred nineteen times

Influenza bacilli occurred two times

Friedländer's bacillus occurred two times

Micrococcus catarrhalis occurred once

The streptococcus was the most constant organism present, usually accompanied by the pneumococcus

The influenza bacillus was rarely found, and then only in small number, although in some of the cases cultures were made early in the disease, when they are most likely to be found It seems to us improbable, therefore, that the influenza bacillus played an important rôle in the epidemic

PRESCRIPTION WRITING IN ENGLISH*

BERNARD FANTUS, M D
Professor of Pharmacology and Therapeutics, University of Illinois, College of Medicine
CHICAGO

In the report of medical curriculum of the Council on Medical Education of the American Medical Association, the following position is taken by the Subcommittee on Prescription Writing concerning the use of Latin [1]

> The committee considers Latin desirable for the names of ingredients (inscription), indifferent as to the directions to the dispenser (subscription), and objectionable as to the directions to the patient (signature) The student should, however, know the meaning of the Latin phrases which are commonly used This amount of Latin may be readily taught in the course, so far as this subject is concerned

While this report was not acted on by the Council, it may be considered the most recent authoritative statement in this matter It commits us to the use of Latin in at least a portion of the prescription

The arguments advanced in favor of Latin prescription writing are as follows

> 1 "The Latin names of drugs are more definite, concise and unchangeable"
>
> 2 "A Latin prescription can be compounded all over the civilized world"
>
> 3 "Latin prescriptions are used internationally in medical literature"
>
> 4 "It guards the patient against knowledge that might be prejudicial (*a*) as to the physician's intention, (*b*) as to greater ease in securing the prescribed drug without a prescription, with possible formation of habit or other detriment"
>
> 5 Better form is preserved "To encourage the use of English official names would easily lead to the use of unofficial English, or common names, which often are indefinite, less pains would be required in mastering the art, and the results would be probably greater laxity in prescribing and less familiarity with the official substances"

Let us analyze these arguments

1 The first reason advanced cannot stand, as the *English official names for drugs and preparations are just as definite and concise as are the Latin names,* and the latter are no less changeable, as is evidenced by the changes in the official names occurring at pharmacopeial revisions We must not confuse, in this connection, the English *official* names, which are given in the pharmacopeia alongside of the official Latin names, with the common English names, or synonyms, such as Paregoric, Hoffmann's anodyne, Epsom salt, golden seal, Indian hemp, etc, which often are given in the pharmacopeia after the official English name

2 As to the second reason, it may be considered very *doubtful whether it is ever desirable for a patient traveling abroad to have a prescription refilled without medical supervision* Even when the patient stays at home, indiscriminate refilling of prescriptions is not desirable When the patient travels, there is added the lack of international uniformity of strength of preparations (excepting in the case of some of the poisonous medicaments) that might lead to undesirable results, if a prescription calling for a U S P preparation were filled with a preparation of another pharmacopeia having the same or similar name, but a different strength

---

* From the Pharmacologic Laboratory, University of Illinois, College of Medicine

[1] Report of Subcommittee on Pharmacology, Toxicology and Therapeutics Section 4 of Report of Committee on *Standard Curriculum for Medical Colleges*, American Medical Association, p 7

That there is a considerable disparity in the strength of preparations of various pharmacopeias may be seen from the few examples given in Tables 1 and 2 That there are not only differences in strength, but even qualitative differences in composition, may be seen from the fact that the compound infusion of senna contains magnesium sulphate in the United States and British pharmacopeias, and potassium and sodium tartrate in the German and various other continental pharmacopeias There is also a considerable difference in the use of correctives, but, most of all, a decided difference in strength the United States preparation representing, for instance, 6 per cent of senna, while the Austrian preparation represents 12 per cent Fancy the predicament of a traveler who buys his compound effervescing powders or compound infusion of senna in different countries, he is doomed to either disappointment or discomfort With troches of santonin, wine of colchicum, tincture of lobelia, or fluidextract of nux vomica, the result might easily be worse

TABLE 1 —STRENGTHS OF PREPARATIONS IN VARIOUS PHARMACOPEIAS GIVEN IN PERCENTAGE OF ACTIVE INGREDIENT

	U S	German	British	Others
Liquor sodii hydroxidi	5	15	20 0	
Oleum phosphoratum			1 0	0 1*
Syrupus ferri iodidi	5	5	5 0	0 5‖
Spiritus aetheris nitrosi	4		1 52 to 2 66	
Fluidextractum nucis vomicae strychnin	1 0		1 5	
Tinctura lobeliae	10 0		20 0	
Tinctura iodi	7 0	10 0	2 5† 10 0‡	
Unguentum sulphuris	15 0	33 0	10 0	
Vinum colchici	10 0§		20 0¶	
Vinum ipecacuanhae	10 0		5 0	

* Austrian
‖ French
† Mitis.

Antimonii et potassii tartras	Tartarus stibiatus—German

3 International use of Latin in medical literature would be an argument of some importance in favor of Latin prescription writing, but, as can readily be shown, the *Latin names of drugs are far from being international* Examples are given in Table 3 -

Any one who reads and understands English well enough to study English literature would surely have no difficulty in understanding a prescription written in English Should other nations retaliate by using their language instead of Latin, that would hardly require a greater knowledge of the foreign tongue than would be needed for the use of the literature of that language Should, however, the other nations persist in the use of Latin, the knowledge needed to translate these prescriptions into English would be much more easily acquired than the ability to write Latin prescriptions correctly In point of fact, however, as one looks over current literature, in various languages, one finds very few Latin prescriptions Generally, whenever medicines are mentioned, in German, French or English literature, dosage and method of administration are discussed in the language in which the article is written and not in Latin

4 Inasmuch as it is the popular opinion that doctors use Latin in prescription writing to keep the laity in ignorance for selfish ends, it seems high time that we antagonize this idea, and we can do this most emphatically by using English This we can also do with perfect safety, for *secrecy is very rarely, if ever, essential* in the practice of the up-to-date physician, who generally prefers to take his patient into his confidence than to keep him in ignorance Deception is not practiced by the true physician Therein lies the special difference between the quack and the honest medical man Furthermore, Latin prescription writing does not really contribute much more to secrecy than the use of English, for the *Latin and English official terms for drugs and preparations are often identical, generally very similar to each other* So similar are they, that certain books on prescription writing advocate the use of synonyms, as pulvis Doveri, liquor Fowleri, etc, when it is undesirable in the patient's own interest for him to become acquainted with the treatment When it is stated that self-medication might be encouraged by the use of English, I fail to see the force of the argument Is the patient more likely to call for sodium bromid at the drug store when it is written “sod brom,” standing for sodium bromid, than when it is intended to read “sodii bromidi”?

ILLUSTRATIVE PRESCRIPTIONS

Prescription in Latin	Prescription in English
gm vel c c	gm or c c.
℞ Ammonii chloridi 5	℞ Ammonium chloride 5
Syrupi ipecacuanhae 8	Syrup of ipecac 8
Aquae q s ad 60	Water to make 60|0
Misce et fiat solutio	Mix and make solution
Signa Teaspoonful in water every two hours	Label Teaspoonful in water every two hours.

Prescription in Latin	Prescription in English
gm vel c c.	gm or c c
℞ Hydrargyri chloridi mitis |06	℞ Mild mercurous chloride |06
Sacchari lactis 2	Sugar of milk 2
Misce et divide in chartulas x.	Mix and divide into ten powders

℞ Morphinae sulphatis	℞ Morphine sulphate
Extracti belladonnae ana |12	Ext of belladonna each |12
Olei theobromatis 24	Oil of theobroma 24
Misce et divide in suppositoria xii	Mix and divide into twelve suppositories
Signa One every four hours, as needed.	Label One every four hours as needed

That, with few exceptions, the use of English gives the patient no more and no less information than the use of Latin, may be seen from the accompanying illustrative prescriptions

In respect to the fifth reason, all that seems to be necessary is to call attention to the fact that the time allotted to the teaching of pharmacology and therapeutics is extremely limited, actually insufficient to teach the essentials Is it not reasonable to suppose that a conscientious teacher, freed of the necessity of burdening his course with the teaching of Latin forms, would have more time to spare for the more important facts in connection with prescribing? Surely, making a subject more complicated does not lead to a better mastery of it

It has been my experience that the teaching of Latin prescription writing makes it difficult to get *into* the students minds the really *important* facts about prescribing, namely, the "art of prescribing," or more specifically, the "technic of medication," which has nothing to do with the language used This is a matter that is not sufficiently studied by medical students or practitioners, and it is not improbable that focusing attention on the mere language of the prescription causes the really important question relating to the most efficient and most pleasant administration of the remedy frequently to be lost sight of

It is true that students now come to us with better preliminary training than was formerly the case, it is also true, however, that even a professor of classical Latin would have to learn our prescription "Latin" almost as if he had not studied Latin before, for the Latin of prescriptions consists essentially of Latinized modern terms One can find but few of them in a dictionary of classical Latin

That the teaching of Latin prescription writing has so far contributed but little toward the preservation of good form will be admitted by any one who has had experience behind the prescription counter An investigation[2] which I conducted on the quality of prescription writing in this country, to which 100 leading pharmacists in various sections of this country contributed and which represented an examination of 10,000 prescriptions, showed that less than one half of all prescriptions are written in correct Latin form, 36 per cent of all prescriptions being written in English and 18 per cent in poor Latin If there is any error in this compilation — and it must be admitted that modern pharmacists generally have merely a knowledge of what might be called "prescription Latin," it is likely to be in the way of overlooking minor errors in Latin, so that probably much less than half of all prescriptions are written in correct Latin form — surely a poor showing for the time and energy invested in teaching Latin prescription writing

Even the Latin prescriptions published in current medical literature, in periodicals as well as in textbooks, including those published in some books on prescription writing, contain enough errors to make their authors blush were they pointed out to them Would it not be better to have prescriptions written in correct English than to have them written in the slipshod and at times ridiculous way in which so many of them are written at present?

While, therefore, none of the arguments in favor of Latin prescription writing can be said to be irrefutable, a number of arguments in favor of English prescription writing deserve consideration

1 The Roman numerals, especially I and L (standing for 1 and 50) are apt to be mistaken for each other, while our common numerals are much more distinct from each other in appearance (E G Eberle)

2 Few of us are sufficiently versed in Latin to be able to express directions to the pharmacist that are in any way unusual Even if we were capable of writing such directions in Latin, not one druggist in a hundred would be able to understand them Unusual directions to the pharmacist are, therefore, generally written in English, even in Latin prescriptions, which, though endorsed in the committee report quoted above, is really less correct than using either language throughout

3 New drugs are continually being introduced, the coining of the Latin names for which is an embarrassment to the prescriber

4 It is probable that the fear of making mistakes in the Latin form is one of the contributing causes to that therapeutic abomination, the prescribing of readymade official or proprietary mixtures *Latin prescription writing absolutely stifles originality in prescribing*

5 After all, the whole proposition of writing prescriptions in Latin is a pretense at a knowledge of Latin, of which most of us possess so little that we would be unwilling to have our ability tested by one who is a recognized authority in that language Encouraging students to think that it is a creditable thing to shine in a veneer of knowledge as superficial as that of Latin usually is cannot but have a detrimental effect on the inculcation of the principle of thoroughness that should guide all good teaching

6 By far the most important reason for writing prescriptions in English lies in the difficulty medical students have in learning the Latin form To the student, prescription writing is a bugbear When one thinks of the crowded medical curriculum and the comparatively small number of hours set aside for pharmacology and therapeutics, it seems a pity to waste any of it on the acquiring of an antiquated form of expression

It appears that the real reason for prescription writing in Latin is historic It originated in the days when Latin was the chief medium for exchange of scientific thought No longer, however, are scientific lectures delivered in the Latin tongue, no longer are medical books written in Latin, no longer is it considered essential for an educated man to speak Latin, and yet we still feel bound to write prescriptions in that dead language Is it not time to relieve our medical students of this useless burden that is put on them to the detriment of something else that would be much more useful to them and to their patients? *Let us at least admit that a prescription correctly written in official English is as good as one written in Latin* Let us permit students and practitioners to use whatever form they prefer, and let us merely hold our students for a sufficient knowledge of the Latin form to enable them to translate and understand such prescriptions

A DIGEST OF REPLIES TO QUESTIONNAIRE ON PRESCRIPTION WRITING IN ENGLISH

A preliminary draft of this article was sent to leading medical teachers, to deans of schools of pharmacy, and to secretaries of state boards of health For the numerous replies obtained in return, and, most especially for a number of suggestions received from some of those in favor as well as some of those opposed to the proposition, I wish to express my sincere thanks An analysis of the reports gives the following results

---

[2] Fantus, Bernard What Instruction Ought Medical Colleges to Give in Pharmacology and Therapeutics, Part B of Symposium The Viewpoint of the Pharmacist, Quart Fed State Med Boards of U S, 1914, p 293

Of sixteen deans of colleges of pharmacy who responded, ten were in favor of the proposition, four were opposed, and two were neutral

Among ninety-two medical teachers, who responded, sixty-seven were in favor, twenty-two opposed, and three neutral

In two institutions, the question of prescription writing in English was taken up in faculty meeting The faculty of the School of Medicine of Yale University voted, Jan 24, 1916, that "it was the sense of the faculty that English be the language of choice in instruction in prescription writing" The faculty of the University of Michigan, on the other hand, passed a resolution, Jan 25, 1916, opposing the writing of prescriptions in English In its opinion, more time, instead of less, should be given to Latin

An interesting reply was received from Prof Gabriel Casuso, president of the University of Havana, Cuba, from which I quote "I believe you are right in every respect — among us, the laws governing the matter, although they do not restrain the use of Latin, allow the employ of the vernacular tongue, and the pharmacists are not obliged to dispense prescriptions unless they are written in plain Spanish "

To secretaries of state boards of health, the question was sent, "Would your examining board give a candidate a low grade, should he, in an examination, write a prescription in correct English instead of writing it in Latin"?

In reply to this, the following state boards expressed, through their secretaries, presidents or examining officers, their willingness to accept prescriptions written in English at the same value as those written in Latin Alaska, Arkansas, California, Connecticut, Florida, Louisiana, Montana, Minnesota, Massachusetts, New Mexico, Ohio, Rhode Island, Virginia, Vermont, Wisconsin and West Virginia

The following state boards have declared their objection to prescription writing in English Illinois, Iowa and New Jersey This makes a total of sixteen in favor, and three opposed

From this it will be seen that the sentiment in favor of English prescription writing is surprisingly general

A CASE OF TORSION OF THE SPERMATIC CORD WITH TERATOMA OF THE TESTICLE*

J W Babcock, M D, New York

The combination of torsion of the spermatic cord with a new growth of the testicle seems so unusual as to warrant a report of this case The search of the records of a few years which were available to me failed to reveal a report of this particular association of lesions, though, doubtless, it is not unique

The subsequent course of the case should also be of interest for the patient was operated on sixty-one days after the first symptom referable to the tumor of the testicle only the more acute symptoms of torsion however, causing him to consult a physician The bad prognosis of new growth of the testicle we hope will not apply to this case on account of its early radical treatment Bulkley[1] gives a record of eight deaths within one year following operation for malignant disease of the testicle, in fifteen cases, or 53⅓ per cent , and only two of these patients, or 13⅓ per cent, were known to be alive and well after two years Nearly all the other reported cases of malignant disease of the testicle are supplemented by accounts of subsequent and early death with recurrence, usually distant metastases In the case reported the patient was seen five months after operation, and at that time showed no symptoms or signs of recurrence

CASE REPORT

History—C C, man, white, aged 24, clerk, admitted to Presbyterian Hospital Oct 8, 1915, injured the left testicle with his thigh six weeks before in sitting down, causing only slight pain The next day a slight swelling of the left testicle was noted, which continued without appreciable change and was accompanied by slight soreness in the left testicle, radiating up to the left hip and lumbar region, but not incapacitating him

On the morning of admission, on stretching after getting out of bed, he was seized with an excruciating pain in the left testicle, and the testicle became hard and tender He was seen by a physician, who said it was a hernia, and manipulated it without relief There were no general symptoms

The patient's past and family histories were negative, except that he had a small left inguinal hernia six years ago, which disappeared after wearing a truss for one year Venereal disease was denied

Examination—The patient was well developed He suffered acute pain The left testicle was twice the size of the right and slightly tender, the left epididymis was posterior, slightly swollen and extremely tender A tiny cystic mass was palpable just above the globus major The spermatic cord was slightly thickened, not nodular, and very tender up to the internal abdominal ring Rectal examination was negative There was no discharge from the meatus

Temperature, pulse and respirations were negative Blood count showed 16,000 white blood cells with 88 per cent polymorphonuclears Examination of the urine was negative

Treatment and Course—The patient experienced great relief from pain after use of support to scrotum, an ice cap and ichthyol The swelling, however, increased somewhat in size, owing to a collection of fluid in the tunica vaginalis Some difficulty was experienced in reaching a diagnosis, but finally acute epididymitis and orchitis, with the possibility of an underlying tuberculosis of the epididymis was considered most probable, and the patient was allowed to go home, Oct 16 1915, to continue conservative treatment It is interesting to note that the correct diagnosis was considered and thought improbable

The patient was readmitted, Oct 26, 1915, having had a sudden increase in his pain and the swelling six days before relieved somewhat by aspiration of a small amount of clear yellow fluid from the tunica vaginalis

Physical examination then showed a firm, moderately tender mass in the left side of the scrotum not so heavy as solid tumors usually are, and showing a small amount of fluid without great tension, in the tunica vaginalis The tenderness extended along a somewhat thickened and nodular cord up to 1 inch beyond the external abdominal ring Rectal examination was negative

Operation—Next day, by courtesy of Dr S Burnap, I performed a left orchidectomy with high ligation of the cord with the following findings There was a moderate amount of serous fluid in the tunica vaginalis The testicle was enlarged to about 2 inches in diameter, and on exploratory incision yielded only a few drops of dark blood The epididymis was brown and not enlarged The testicle was rotated 360 degrees counter-clockwise and the veins in the spermatic cord above the twist were firmly thrombosed There was no definite gangrene, and the existence of the teratoma was not suspected, but relief of the torsion did not improve the circulation and the torsion showed a tendency to recur so orchidectomy was deemed advisable

The patient made a satisfactory recovery with no complications, and was examined five months later, when he showed no symptoms or signs of recurrence

---

* From the service of Dr E Eliot Jr at the Presbyterian Hospital in the City of New York, by permission of Dr G E Brewer Surgical Director

[1] Bulkley K Malignant Disease of Retained Testicle Surg Gynec. and Obst 1913 xvii 703

Pathologic Report (by Dr F B St John)—The specimen consists of a testicle and epididymis measuring 5 5, 5 5 by 4 5 cm, with 4 5 cm of spermatic cord Part of the wall of the tunica vaginalis is hemorrhagic The surface of the testicle is shiny, reddish gray and smooth It is rather soft and fluctuating in consistency

Microscopic examination shows a normal testicular glandular arrangement, but the testicle proper is largely replaced by connective tissue, in the center of which is a large area of cells, made up almost entirely of cartilage cells The periphery of this area seems to merge indefinitely into surrounding connective tissue Outside of this rather dense central area is a large area of polymorphonuclear infiltration and round cells, beyond which is definite necrosis, consisting of poorly stained cell debris

Diagnosis—Teratoma of testicle with acute inflammation

75 East Eighty-First Street

HEMORRHAGIC CONDITIONS

(*Continued from p 1623*)

HEMOPHILIA (BLEEDERS)

Hemophilia is a condition, usually hereditary, characterized by a decrease in the coagulation time of the blood and frequently resulting in death from hemorrhage The hemorrhage may be spontaneous, or it may be initiated by a cut, bruise or blow The bleeding is not limited to any part of the body

Hemophiliacs, commonly known as "bleeders," are of the male sex Female "bleeders" have been reported occasionally, but not enough evidence is furnished to show that these are true hemophiliacs Hess[1] characterizes some of these cases in females as hereditary purpura The disease is transmitted through the female members of the families to their male offspring Such cases can be traced through generations of families, several male members, but not all necessarily, of one generation being affected Often the hemophilic tendency will make its appearance early in infancy, occurring at birth when the umbilical cord is severed J E Welch[2] mentions such cases, and also bleeding from other parts in the new-born under the name of "hemophilia neonatorum"

Various theories have been advanced as to the etiology of this condition These can be divided into two groups (1) deficiency in one or more of the blood elements, and (2) deficiency in the elements of the cells of the blood vessel walls In the first group the hemorrhage has been attributed to lack of calcium, deficiency or prothrombin, or to an excess of antithrombin Weil[3] has even claimed the presence of anticoagulants in the blood On the other hand, it has been asserted that there is abnormal fragility of the blood vessel or that there is lacking in the cells of the wall a fibrin-forming substance — thrombokinase No doubt cases may be found that are explainable by any of these theories

Certain factors relating to the blood in hemophilia have been definitely proved It has been repeatedly shown that the coagulation time of the blood is prolonged Normally blood will coagulate in from ten to twenty minutes, with the same methods for determining coagulation time of the blood in hemophiliacs, it has been shown that the coagulation time may be prolonged for as long as five hours Hess states that the coagulation time should be taken at different periods, since occasionally it may approach normal It is probable that on the occasions when it approaches normal there is admixture of juices containing thrombokinase from tissue at the site of puncture Duke[4] and others have shown that the blood platelet count in hemophilia does not vary from the normal, whereas in purpura hemorrhagica it is lower than normal In exceptional cases, such as one mentioned by Hess, the calcium content has been found unchanged Howell[5] found a deficiency in prothrombin, the antithrombin being normal or only slightly increased

A hemophiliac may be unrecognized until hemorrhage occurs, from any cause or spontaneously Profuse epistaxis is frequent, or severe hemorrhage may follow tooth extraction, or there may be bleeding into the stomach or intestines The hemorrhage may be subcutaneous, following blows, and resulting in the formation of hematomas A well known symptom of hemophilia is effusion into the joints The larger joints are most often affected, particularly the elbow, knee or ankle joint This hemarthrosis may first manifest itself by pain in the joint, soon followed by swelling Occasionally fever is associated with it The true nature of the condition is often not diagnosed, a common diagnosis being articular rheumatism or tuberculous arthritis Operations based on incorrect diagnoses have resulted fatally If the joints are not opened, but are treated gently by massage or heat, the effusion of blood disappears, sometimes within a few days, or sometimes only after weeks or months Recurrences may follow, but the tendency for this grows less as the patient becomes older Following one absorption of blood there may be a partial ankylosis

TREATMENT

The treatment of hemophilia up to within a recent period has been as varied as the theories of its cause Recently it has become more uniform because of successful experiences covering a large number of cases Treatment may be general and local It depends to a great degree on the location of the hemorrhage If there has been considerable loss of blood, the patient should be supplied with sufficient fluids to help make up this loss Milk is recommended, both on account of its calcium content and because of its nutritive value If marked anemia is present, iron in convenient form should be given This may be administered by the saccharated oxid, in 3-grain tablet, crushed with the teeth before swallowing, one tablet two or three times a day, after meals, as the reduced iron in 0 10 gm dose, in capsule, two or three times a day, after meals, the Blaud pill, 3 grains, two or three times a day, after meals, or the tincture of the chlorid of iron in 5-drop doses, in fresh lemonade or orangeade, three times a day, after meals As has frequently been stated, there is no advantage in an organic iron over an inorganic iron, and there is no necessity of giving large doses of iron in simple anemia

For directly diminishing the coagulation time of the blood two methods have been tried The first consists of the administration of empiric remedies supposed to supply one of the missing factors necessary for coagulation Calcium in some form is frequently of benefit in these cases It may be administered as simple lime water in tablespoonful doses, three or four times a day, given in milk or in water, or as calcium lactate, in dose of 0 3 gm (5 grains) given in some solution three or four times a day Calcium chlorid is perhaps most frequently used, but it is more irritant and of no greater efficiency than other forms of calcium The dose should be about 0 3 gm , given very well diluted, and three or four times a day, as desired This form of calcium is more likely to upset the stomach than are other forms

[5] Howell, W H The Condition of the Blood in Hemophilia Thrombosis and Purpura, Arch Int Med, January, 1914, p 76

Another remedy used for local application is epinephrin Its value is based on its vasoconstricting action In hemophilia it has been tried without apparent success

The best results obtained have followed the use of serums Various kinds have been administered, among which are rabbit, horse and normal human serum The serum has been used in different forms freshly obtained from the blood in the form of plain horse serum or weak preparations of diphtheritic antitoxin when other serum is not available, also solutions of the dried serum Of late controversy concerning serum therapy has been confined mainly to the kind of serum producing the best results All are agreed as to the value of serum in hemophilia

Serum may be administered intravenously, subcutaneously, or applied locally to the bleeding point, if it can be reached When given intravenously or subcutaneously, proper aseptic precautions should be taken For intravenous injection, from 10 to 20 c c can be given every day until the bleeding stops, whereas for subcutaneous injection this dose should be doubled The intravenous injection has great advantage over other methods, since by mixing intimately with blood it supplies more rapidly the absent elements necessary to increase the coagulability of the blood When given subcutaneously, the serum must first be absorbed into the blood stream from the tissues, and before this can occur it will probably undergo a certain amount of change from action by the tissue cells

Normal human serum, if this can be obtained, is without doubt the best to use, since it contains no foreign proteins Cooley[6] suggests that "the blood-forming tissues react to the stimulus of normal serum (or blood) by the formation of normal blood and that possibly there is a reaction between normal blood and the vessel-walls, lacking in certain abnormal states, which explains the complete cessation of hemorrhage "

It has been found that following the administration of either rabbit, or more particularly, horse serum there occasionally follows definite symptoms to which has been given the name "serum sickness " This consists of a rise in temperature and the formation of an urticarial rash, the rash often being surrounded by an area of edema The urticarial rash often fades into a scarlatiniform rash that lasts for several days

Horse serum (or diphtheritic antitoxin) is the most convenient form, as it is readily obtainable There must be borne in mind, however, the possibility of anaphylactic shock, which should be carefully considered before the serum is administered to those patients who have more or less recently received injections of antitoxin Also, before any horse serum is injected it should be known that the patient does not suffer from hay-fever or asthma from horse emanations

Unless proper agglutination and hemolysis tests are first carried out, just as they are for transfusions, whole blood should not be injected into the veins

Good results have been reported from the use of tissue extracts applied locally to the bleeding point These tissue extracts have been thyroid, ovary, liver, pancreas, kidney and spleen The thyroid extract has been used most frequently No good reason has been offered for the hemostatic properties of tissue extracts Not infrequently profuse hemorrhages have been stopped by the administration of thyroid While thyroid extract increases a liability to hemorrhage in most individuals, and may even cause menstruation or increased menstrual flow in some instances, in hemophiliacs it has at times been successful in stopping bleeding when other treatments have failed Also, occasionally in profuse bleeding occurring at the time of the menopause, thyroid substance given in large doses, as much as 4 grains of the desiccated thyroid three or four times a day for a few days and then the dose reduced, has stopped bleeding when all other medication has failed

As a last resort, transfusion itself may be tried The usual precautions should be taken, the blood of both patient and donor being tested for hemolytic and agglutinative properties A Wassermann test of the donor's blood should also be made Ottenberg and Libman[7] state that "every individual known to have hemophilia ought to have at his command several persons whose blood, by previous tests, is known to be compatible with his and who are willing, when called on, to give blood for transfusion " If these blood tests have been made a long time before, the character of the blood may have changed, therefore such tests should not be relied on, but fresh tests should be made They also state that in transfusions some blood element is supplied that has been lacking, and on that account the cure is not always permanent as the supply is only temporary They report a series of five hemophiliacs who were transfused, and in every case the hemorrhage stopped after transfusion

Inasmuch as there is a high mortality in hemophilia, unless the hemorrhage is promptly and completely checked, advantage should be taken of every available means to obtain serum or to make arrangement for a transfusion If there is no source from which fresh serum can be obtained, and if for any reason transfusion cannot be done, horse serum or antidiphtheritic serum, which can always be procured, should be injected We would also refer a physician interested in this subject to a recent article by Hurwitz and Lucas (*Arch Int Med* , April, 1916, p 543)

THE RESTORATION OF THE BLOOD VOLUME AFTER HEMORRHAGE

Any considerable diminution of the total volume of the blood, as by bleeding, would obviously lead to serious consequences unless compensatory activities of some sort promptly ensued. Any resulting depression of the circulation through the brain, for example, would speedily be attended with deleterious effects of a far reaching character. Fortunately this is usually averted in part by the general vascular constriction which follows hemorrhage, diminishing the total capacity of the circulatory system and altering the distribution of pressures throughout it. In addition to this response, the deficiency of blood caused by removal of this fluid is soon remedied by a transfer of fluid from the tissues to the blood. The exchange goes on with surprising rapidity, often beginning even during the course of the hemorrhage.

How this transfer is accomplished has been somewhat of a physiologic puzzle. The passage goes on far too rapidly to be accounted for by the slow flow of lymph into the blood stream, and for a variety of additional reasons this factor can be excluded as being of primary significance. It was suggested by Landerer[1] that when the pressure in the blood capillaries falls, as the result of hemorrhage, below that in the tissue spaces, the fluid present there is forced back into the capillaries. This is the so-called backward filtration theory. According to Starling,[2] on the other hand, there is normally a balance in the production and absorption of tissue fluid between the filtration pressure in the capillaries and the osmotic pressure of the colloids of the blood and tissue fluid. Plasma and tissue fluid are practically identical in their composition in everything except protein. Starling showed that the blood proteins exert an osmotic pressure of about 4 mm. of mercury for every 1 per cent. of protein. Since the plasma contains more protein than the tissue fluid, its osmotic pressure is greater, and this greater osmotic pressure should cause an absorption of fluid when the capillary pressure is reduced.

Dr. F. H. Scott[3] of the University of Minnesota has pointed out that after hemorrhage, if the backward filtration theory is correct, the fluid which enters the blood should have some protein, while according to Starling's theory the fluid should be practically salt solution. Thus it seemed possible that a comparison of the protein content of the blood before hemorrhage and a short time after it might throw light on the nature of the fluid passing into the blood. In a newer investigation of the subject, Scott has indeed found that after hemorrhage an increase occurs in the total protein of the blood plasma, corresponding to a protein content of from 0.6 to 2.01 per cent. in fluid which has passed through the capillary wall from the tissue spaces to the blood. But similar increases of protein may also be observed after injection of Ringer's solution into the blood and when, as a consequence, the injected fluid instead of entering the blood is leaving it for the tissue spaces at a rapid rate. It has been shown that dilution of the blood in vitro with isotonic salt solutions may lead to an increase of the nitrogen in the plasma. The gain must, of course, be derived from the corpuscles. The dilution of the blood in the circulation itself, caused by the intake of fluid from the tissue spaces, produces a change similar to that caused by diluting the blood in vitro with isotonic salt solution. In the living circulation the endothelial cells of the blood vessels might also share in the contribution of protein to the diluting fluid. Consequently an increase of protein in the plasma after hemorrhage is no evidence of backward filtration, and is consistent with Starling's view that in restoring the volume of the circulation the fluid passes into the capillaries by osmotic action.

THE STRUCTURE OF THE THYROID IN RELATION TO ITS FUNCTION

Attempts to correlate the functioning of various glandular organs of the body with corresponding alterations in their structural make-up have been frequent in the modern history of the physiology of secretion. In this way it has been demonstrated that the histologic appearance of the cells of the secretory glands which discharge their product into the alimentary tract changes with the state of the glands in respect to rest or activity. The morphologic alterations incident to the secretion of structures of this type are of the same general character, whatever the class of digestive glands that is investigated. In the salivary glands, for example, the resting cells show a mass of highly refractive granules distributed in the protoplasm. After vigorous secretion, the individual cells are as a rule found to be smaller, and the simple protoplasm is relatively increased in amount, while the granules are much fewer and are now confined almost entirely to the inner margins of the cells near which they are ordinarily discharged or converted into secretion. Activity is thus associated with a discharge of granules, and probably with some increased production of protoplasm. As one physiologist has expressed it, we may regard the act of secretion as determined by the alteration of the granules and their discharge, together with water and salts, to form the specific secretion of the gland. During rest the granules are formed anew by precipitation in the protoplasm surrounding the nucleus, or by modification of it. Although the granules form the secretion, presumably they represent, not the secretion as such, but a precursor of some of its constituents.

Inasmuch as the so-called ductless glands of internal secretion, or the endocrine glands, as they have been called of late, show many structural similarities to the familiar secretory glands, there has been a tendency to apply analogies derived from the latter to the functions of the former class. If it were possible to correlate definite changes of structure with functional phenomena, it would, of course, enable one to form some estimate of the "secretory potential" of a gland by a histologic examination of its cells. The thyroid gland contains cells which resemble those of an ordinary secreting gland in many ways, notably with respect to the granules and other cytoplasmic details as well as the arrangement of the cells in the organ. The search for histologic evidences of the secretory activity which is indicated by a variety of physiologic experiences has revealed rather conflicting results. The thyroids are composed of vesicles of different sizes, which are lined by a single layer of cuboidal epithelium and contain in their interior the material known as colloid. Inasmuch as the gland possesses no duct it has been supposed that the cells furnish their specific product, that is, an "internal secretion," to the blood along the lymphatic efferents of the gland. Accordingly, it is stated that the colloid which has been looked on as identical with the active substance of the secretion is formed in the lining epithelial cells, and that the vesicles finally rupture and discharge the colloid into the surrounding lymphatic spaces.

Bensley[1] has recently pointed out how baffling the interpretation of the presence of the storage product in the thyroid has been. The route and rate of absorption of the thyroid colloid have remained problematic after years of observation, though chemical and physiologic studies have indicated that it contains the physiologically active thyroid component. Bensley recalls that some observers have even doubted the resorption of this material, and have suggested that the function of the thyroid gland is primarily to withdraw toxic substances from the blood. Others have conceived the colloid as a sort of menstruum in which the real thyroid secretion is received and from which it may be withdrawn without visible change in the colloid itself. Still others have held the view that the colloid is the real secretion of the thyroid gland, and that the normal mechanism of thyroid secretion is by this indirect route, first secreting into the center of the follicle and then withdrawing this warehoused material, as functional needs require, by some unknown method and route.

The experimental prosecution of investigation in this field is rendered difficult by the fact that few, if any, reliable methods of provoking thyroid function are known, so that it is not easy to decide whether a given gland is in a state of normal activity or hypersecretion. In an elaborate research on the structure of the thyroid as modified by diet and drugs, Bensley[1] has succeeded in demonstrating histologically the presence of what he terms the "secretion antecedent." The substance occurs in vacuoles, present exclusively in the outer pole of the cell, which contain a dilute solution similar in its properties to the colloid of the follicular lumen, differing from the latter only in density. The secretion collected at the outer margin of the thyroid cells is believed to be destined to direct transport into the vascular channels. In accord with its endocrine function, the thyroid cell thus represents a true reversal of "polarity," unlike the exocrine glands of the alimentary tract, discharging its active product away from the real follicular cavity directly into the surrounding medium.

The theory just presented fails, however, to account for the occurrence of the intrafollicular colloid in contact with the inner surfaces of the cells. It has frequently been observed that stored colloid may be withdrawn from the gland in a short period, and that the thyroid may be maintained for months in a condition in which little visible colloid is present. Bensley has reached the conclusion that in addition to the direct mode of secretion already described, there is an indirect mode which consists in the condensation of the secretion into the form of droplets having a high content of solids, and the extrusion of these into the follicular cavity. This implies that when the rate of production exceeds the body needs, the product of secretion is condensed, as it were, and stored as the familiar colloid in the intrafollicular spaces. On this hypothesis iodin, either by accelerating the activity of the gland cells or by inhibiting the removal of the product, causes the cells to reverse their usual processes and store colloid in the cavities.

If Bensley's observations prove to be tenable, the much discussed colloid in the thyroid vesicles is, by itself, no measure of the momentary activity of the gland, though it may indicate the capacity of the gland for storage of its physiologically active secretory product. Conversely, lack of colloid need not imply a permanent depression of actual glandular function, but merely a temporary depletion of storage material Dietary conditions, notably an excess of meat in the ration, may give rise to a condition of hyperplasia of the thyroid gland, iodids, on the other hand, facilitate the storage of colloid[2] These suggestions place the rôle of the thyroid colloid in a new light They permit the known facts, often seemingly contradictory, to be viewed in a new way, and may serve to illuminate what has long been a most perplexing theme

THE INCIDENCE OF BOVINE AND HUMAN TUBERCLE BACILLI IN MAN

The controversy regarding the significance of the bacillus of bovine tuberculosis in relation to human hygiene, carried on ever since Theobald Smith, in 1898, made his systematic comparative study of bacilli isolated from man and cattle and pointed out differences between the two types, has lost much of its acrimony From a practical standpoint it is, of course, very important to learn whether the bovine and human diseases caused by the respective bacilli are mutually interchangeable At present it seems to be agreed that while cattle are to a considerable extent immune against the bacillus of the human type, human beings do not enjoy the same safeguard in respect to the bovine bacillus During adult life, however, the danger of such infection is far less than it is during infancy and early youth[3]

In the extensive investigations of Park and Krumwiede,[4] which have furnished some of the most important data respecting the types of tubercle bacilli which sojourn in the human body, it was found that out of a total of 1,042 cases, only 101 were bovine in origin, and over half of these occurred in children under 5 years of age Incidentally it may be noted that fifty-one out of the fifty-nine cases occurring in the 161 infants examined were directly or indirectly traced to alimentary infection, thus emphasizing the importance of a rigid sanitary control of milk supplies, on which infants are so largely dependent

More recently Eastwood and Griffith,[5] in Great Britain, have made a report of the relative distribution of the various strains of tubercle bacilli in human bone and joint tuberculosis, and likewise, in a smaller number of cases, in tuberculosis of the genito-urinary tract in man For the former investigation the material examined was removed directly from an affected joint or bone, or from an abscess in the neighborhood of such lesion Out of a total of 261 patients, fifty-five, or 21 per cent, were "bovine" cases Ten were recorded as atypical Only three of those reported on as harboring the bovine bacilli were over 16 years of age The incidence of the types is further shown by the fact that whereas under 10 years of age forty-five out of 155 cases, or 29 per cent, were bovine, over 10 years only ten out of 106, or 9 per cent, were of this type

In their report of 1910, Park and Krumwiede[4] described only two bovine cases out of a total of sixty-five cases of tuberculosis of bones and joints Twelve patients with tuberculosis of the genito-urinary tract disclosed only one infection of the bovine variety, the persons examined being adults, with one exception Seventeen cases, which were about equally distributed between the genital organs and the urinary tract, were investigated by the British bacteriologists The bacilli obtained were of the "human" type in fourteen cases, and "bovine" in three, the latter involving affections of the kidneys in persons aged, respectively, 25, 19 and 20 years Investigations of this sort, laborious as they are, seem well worth while from the standpoint of public health propaganda They give added assurance that although human adults are perhaps reasonably insusceptible to bovine infection, this mode of transmission can take place even beyond the years of infancy and childhood, in which the danger is unquestionably great

PELLAGRA IN NASHVILLE

An increase in the morbidity and mortality from pellagra in Nashville, Tenn, since 1911, provided the opportunity for a thorough survey of over half of the city, including 65,000 persons, by a pellagra commission, the results of which have recently been reported by Jobling and Petersen[1] Starting out with no preconceived theory as to the etiology of the disease, the commission gathered data, in more than 500 cases of pellagra, as regards the manifestations of the disease itself, its possible relations to sex, age and race, the season of the year, social and economic conditions, housing, occupation, diet, milk and water supply, parasitic infestation, method of sewage disposal, and previous exposure

The carefully analyzed statistics indicate that women from 20 to 50 years of age are affected from three to four times more frequently than men, though from 50 years on, the two sexes seem equally susceptible, that children, particularly during the second decade of life, are less subject to the disease than adults, that negroes are as susceptible as white people and that among them the mortality is higher, and that the majority of the pellagrins had their attacks during the spring and summer months, the white people more frequently during the spring, the colored people during the summer—a fact of interest in connection with the theory that pellagra is caused by "photodynamic substances"[2] Symptoms referable to the gastro-intestinal tract and nervousness frequently preceded the attacks for weeks or even months

[1] Jobling, James W and Petersen, William The Epidemiology of Pellagra in Nashville, Tenn, Jour Infect Dis, 1916, xviii, 501

Among the possible causes of the disease — some of them given much credit in previous investigations — social and economic conditions, density of population, presence of silicates and absence of lime salts in the water (Alessandrini),[3] a deficiency of proteins in the diet, as regards both quantity and quality, and an excess of carbohydrates,[4] seem not to have been active The social and economic conditions of the areas afflicted with pellagra are not inferior to those of certain areas not so afflicted The water contains lime, and is used indiscriminately by both pellagrins and normal citizens A careful study was made of the diet of the pellagrins Accepting the conclusions of Chittenden[5] and McCay[6] that 40 gm of protein a day are sufficient to sustain life, the investigators found that 66 8 per cent of 421 pellagrins were consuming considerably more than this amount daily From the standpoint of quality, also, the protein diet seemed to be reasonably varied, moreover, the height and development of patients compared favorably with the height and development of normal persons, and men with the same diet as women, with probably greater protein requirements than women, were yet less susceptible to the disease Vitamin-containing substances[7] likewise were being obtained in the form of potatoes, milk, butter, fruit, etc That there was an excess of carbohydrates in the diet of these people was evident, but "it is gradually being supplanted to such a degree in many pellagrous families by wheat flour that it can hardly be considered an etiologic factor"

The significant localization of this disease in certain areas of the city, and the fact that the social and economic conditions in these areas were the same as in other areas not subject to pellagra, pointed directly to the one factor of difference — the method of sewage disposal — as having an etiologic relation to the disease Pellagra was largely confined to the unsewered areas of the city, and of those pellagrins who lived elsewhere, the majority had developed the disease while living in an unsewered neighborhood or on the edge of an unsewered area, or had been in the habit of visiting friends and relatives in an unsewered area The sanitary conditions in the unsewered sections of the city were of the worst In an area of a square mile in which pellagra and typhoid were most prevalent were found 1,500 privies, rarely cleaned and almost never enclosed so as to prevent the entrance of flies These privies were located seldom more than 50 feet and frequently not more than 15 or 20 feet from the kitchens of the houses Two per cent of the kitchens were screened Another significant fact brought out in the survey was that 78 8 per cent of the patients had been in intimate contact with other pellagrins before they themselves had developed the disease Finally, the installation of sewers in certain areas was followed by a decrease in the number of cases of pellagra originating therein, and the isolation of cases in certain institutions in which pellagra had made its appearance seemed to prevent further spread of the disease

The results here outlined are highly interesting indeed, and will exercise much influence on investigation of the problem of pellagra, because they indicate that factors other than deficiencies in diet are concerned

SCIENCE AND PRACTICAL COMMON SENSE

Almost every one who is engaged in scientific work is certain sooner or later to find the impression, among people at large and even among some practitioners of medicine, that there is something unpractical and visionary about so-called scientific knowledge This sentiment crops out in various ways Sometimes it represents "the survival of the idea long held that science is a kind of hobby, chiefly for the men who pursue it, that while it may throw light on the abstruse problems of the universe it is not to be the guide of the practical man, and that its adherents are impractical" It is from such a view that the feeling of a sort of antagonism between science and what is called "common sense" derives its origin Reference is sometimes made to "sound practice" as if it were something quite independent of scientific principles, or even superior to them Another somewhat prevalent conception confuses science with theory, whereby the term "scientific" is regarded as synonymous with theoretical

In a recent discussion[1] of these prevalent tendencies of opinion, it has been pertinently remarked that although theory and hypothesis aid in the development of scientific knowledge, pure theory is not science, nor is science mere theory We wish that this might be more widely appreciated, for it would spare scientific workers from much undeserved criticism Any one who will take the pains to review the history of experience in any field of endeavor can easily convince himself how little of permanence there is in many of the vaunted "common sense" plans, theories or procedures The history of medicine or agriculture, for example, readily furnishes instances of the complete abandonment of "practical" methods discredited by scientific investigation

[1] Science and Common Sense editorial Exper Sta Rec 1916 xxxiv 401

Though the claims of science for wider recognition in the everyday world are becoming more readily accepted, there is much inherited prejudice or temperamental inertia still to be overcome before the omnipresent "busy practical man" will permit the development of an inquiry attitude, a desire to understand Has it not been said that "long-continued practice solidifies opinion and makes it impregnable to evidence, and that we come at length to substitute habit for reason?" Let us understand clearly, then, what are the real claims of science The first aim of any genuine work of science, however popular, says Karl Pearson,[2] ought to be the presentation of such a classification of facts that the reader's mind is irresistibly led to acknowledge a logical sequence — a law which appeals to the reason before it captivates the imagination Let us be quite sure that whenever we come across a conclusion in a scientific work which does not flow from the classification of facts, or which is not directly stated by the author to be an assumption, we are dealing with bad science Good science will always be intelligible to the logically trained mind, if that mind can read and translate the language in which science is written The scientific method is one and the same in all branches, and that method is the method of all logically trained minds

What shall be said of the supposed "practical" competitors of the scientific spirit and the consequences which it portends? The editorial to which reference has already been made[1] deserves to be quoted because of its lucid exposition of the fundamental fallacies in some of the current reactionary ideas Common sense, whether of high or low degree, it says, is in effect a product of reason and judgment applied to the facts and conditions as they are seen It rests on information and its interpretation So does science There is some very bad common sense, as there may be bad science Scientific facts are derived more accurately than personal impressions, by providing conditions which tend to guard against error or misconstruction Because the facts developed by scientific methods are accurate, dependable, unprejudiced, and not influenced by purely local conditions, they furnish a safe basis for intelligent reasoning along either practical or scientific lines The scientific method of deduction is more cautious and more restricted in its generalizations than personal judgment may be, but so far as it goes there is nothing antagonistic in it to good common sense The substitution of facts derived in a manner to make them thoroughly reliable, in the place of current notions, traditions and observations, instead of detracting from the practical value and reliability of personal judgment, strengthens it and makes it a safer basis for action There is no reason why the practical man's judgment should not be based on the best and safest sources of information available, and this is exactly what is taking place, whether it is fully realized or not As a matter of fact, science is becoming more and more an aid to sane and practical judgment in all affairs The more science furnishes the means for intelligent understanding and this understanding becomes disseminated among the people, the more common and reliable may "common sense" be, and the further will it be removed from the elements of mysticism, superstition and dogma Confidence in it will not suffer by reason of this change, for it will then rest on intelligence in the things that actually are, combined with sound judgment and clear thinking

RECENT NECROPSY RECORDS IN THE UNITED STATES

There is evidence that the publicity in respect to the discrepancies between antemortem diagnoses and necropsy findings in the United States, together with the propaganda for more postmortem examinations in hospitals and elsewhere, is beginning to produce a long desired improvement in the situation Statistics gathered only a few years ago by competent investigators showed that the ratio of necropsies to deaths ranged above 25 per cent in only four of seventeen large hospitals in this country[1] Among the institutions surveyed by the committee of the New York Academy of Medicine, the two in America showing the highest percentage of necropsies to deaths were the Johns Hopkins Hospital of Baltimore, with a record of 62 7 per cent, and the Royal Victoria Hospital of Montreal, with a ratio of 67 6 per cent These figures have been contrasted with the decidedly higher postmortem statistics from European public hospitals of similar status

The desirability of checking diagnoses and the results of operative procedures by the necropsy findings needs only to be stated to most thoughtful practitioners in order to be appreciated In pointing out the value of the necropsy as a public service, Wilson[2] of the Mayo Clinic has remarked that some physicians entirely lack an interest in necropsies because they are not interested in accurate vital statistics and in problems of heredity in disease, or because they do not appreciate the value of the necropsy in the correction of errors of diagnosis Possibly some also hesitate, as Wilson remarks, to bring their diagnoses or operative procedures to the test of publicity in the necropsy Furthermore, he contends that most intelligent laymen will respond to the argument that they ought to know the weaknesses of the members of their own families, but this argument is frequently omitted or subordinated by the physician proposing that a necropsy be made Usually necropsies are asked for as a favor to the physician and rarely offered as a favor to the relatives

---

[1] Report of Public Health, Hospital and Budget Committee, New York Academy of Medicine, The Journal A M A, June 7, 1913, p 1784

[2] Wilson, L B The Necropsy as a Public Service, The Journal A M A, May 8, 1915, p 1560

The continued awakening in the matter of necropsies is indicated by some new statistics called forth by an editorial comment[3] in the *Modern Hospital* stating that one hospital in America had been successful in obtaining permission for postmortem examination in 58.5 per cent. of the patients dying there. The director of the Pathologic Institute of the Cincinnati General Hospital, Dr. Paul G. Wooley,[4] now reports that between June 1 and Dec. 31, 1915, 293 necropsies were held from a total of 465 cases—a percentage of 63. This improvement is ascribed in part to better cooperation between the undertakers and representatives of the institute staff. The value of the better opportunities for the intensive study of clinical cases from the anatomic standpoint is stated to be demonstrated already. For the Robert B. Brigham Hospital of Boston, Dr. F. H. McCrudden[5] likewise reports that since its opening, April 1, 1914, complete necropsies have been carried out on 70 per cent. of all those dying, that is, thirty-five necropsies for fifty deaths. We shall look forward to a succession of advances over even these greatly improved records. That this is not impossible of achievement is suggested by the reports of the Mayo Clinic.[2] Under the more favorable conditions developed there, 512 necropsies in 626 deaths, or 81.8 per cent., were made during the triennial period 1910-1912; in 1913 they represented 84.4 per cent. of 269 deaths; in 1914, 88 per cent. out of 293, while in the early months of 1915 there were 73 necropsies for 73 deaths — a remarkable record of achievement in the face of the existing obstacles.

Current Comment

THE BABY'S CHANCE FOR LIFE

"No community with an infant mortality rate of over 50 can claim that its babies are getting anything like a square deal." This statement accompanies a statistical bulletin and chart recently sent out by the New York Milk Committee, showing infant mortality rates in a large number of cities in the United States. The committee sent a questionnaire to the health officers of 252 cities. Of these, 108 either furnished no information or were unable to furnish any that was reliable. The statistics obtained from the 144 cities that furnished information are embodied in the committee's bulletin. According to these figures, only four of the 144 cities are giving babies "a square deal." These cities, with their infant death rates, are La Crosse, Wis. (30.6), Ogden, Utah (39.8), Omaha, (47.1), and East Orange, N. J. (48.8). The highest infant death rate in the whole series is that of Passaic, N. J. (193.5), but in this "bad eminence" Passaic is closely rivaled by Montgomery, Ala. (185.1), Nashville, Tenn. (182.3), and Perth Amboy, N. J. (176.6). No city with a population of 200,000 or over has an infant death rate as large as those just mentioned, but not one of them has the "square deal" rate of 50, and few even approach this limit. The lowest rates among cities of this class are those of Seattle, Wash. (53.1) and Portland, Ore. (57.7). The highest are those of Jersey City, N. J. (132.9) and Indianapolis (131.6). To quote the bulletin: "Of the cities with a population of 100,000 or more, a baby born in Omaha was found to have four times as good a chance to live to celebrate the first anniversary of its birth as a baby born in Nashville, Tenn., or Fall River, Mass. In the cities under 100,000 and over 50,000 population, a Salt Lake City baby has over three times the chance of surviving the first year of life that a Passaic, N. J., or Holyoke, Mass., baby has, while in cities between 25,000 and 50,000 population a La Crosse, Wis., baby has an advantage more than six to one over a Montgomery, Ala., or Perth Amboy, N. J., baby." The conditions that cause these high rates may be remedied by any community that is determined not to tolerate this waste of infant life. For instance, of the 6,900 infant deaths that occurred last year in the Borough of Manhattan, New York, alone, over half—at least 3,500—may be classed as preventable if the New York Milk Committee's rate of 50 be accepted as normal. If only six babies in the Borough of Manhattan were to be killed or even threatened with death by a bomb from an aeroplane, the country would be aflame with indignation. An observer from Mars might find this phenomenon curious when placed by the side of the calm unconcern with which we regard conditions that doom to death thousands on thousands of infants in this country.

TUITION FEES AND THE COST OF TEACHING MEDICINE

The rapid increase in medical knowledge during the last quarter of a century has led to the complete reorganization which methods of teaching medicine have undergone in recent years. This reorganization required the establishing by each school of special laboratories equipped with expensive and technical apparatus, and the payment of fair salaries to full time skilled teachers. Instead of generous profits to the proprietors of medical schools, which was the case only a short time ago, the adequate maintenance of a medical school at present requires the expenditure of more money than can be obtained from even the most exorbitant tuition fees. As shown in a report published recently,[1] the total expenditure for teaching in eighty-two medical colleges from which reports were obtained was about five and a half million dollars, as compared with less than two million dollars obtained from tuition fees. In other words, the average cost of teaching each student enrolled in the eighty-two colleges reporting was $419, as compared with $150, the average amount received from each student in tuition fees. Notwithstanding this greatly increased expenditure, tuition fees have been only moderately increased The average tuition fee in all existing colleges is about $145, as compared with $109, the average fee charged by the same colleges fifteen years ago Tuition fees have been advanced by only about 25 per cent in the last fifteen years, therefore, although the cost of teaching has been advanced from the point at which students' fees permitted a profit, to the present situation where it exceeds the income from students' fees by 280 per cent This excess in expenditures has, of course, been met by state appropriations or by private gifts and endowments which, meanwhile, have not been obtained by the small and rapidly diminishing number of medical colleges still conducted for the direct benefit of their owners Such aid has invariably been furnished to the medical colleges which were worthy of it — colleges which were furnishing the best medical training possible with the funds at their disposal

HIGHER TUITION, SCHOLARSHIPS AND NEEDY STUDENTS

The increased tuition fees, referred to in the preceding comment, have caused the publication of occasional statements expressing concern lest a medical education hereafter will be available only to wealthy students There is still no occasion to feel alarmed, however, regarding opportunities for deserving but needy students to enter on the study of medicine In a previous comment,[1] attention was called to opportunities for such students to work their way through the medical school in whole or in part It was shown that as a rule the majority of such students were found in the higher grade and better equipped medical schools, and that the best opportunities for student service were found in such colleges In a later comment[2] it was stated that the attempt to earn all expenses while doing justice to the exacting work of the medical course meant a strain which few could endure, and that the solution of the problem of the "poor boy" lay in free scholarships to be awarded to good students of limited means It was shown that 170 such scholarships had already been provided and that others were being added A report on another page[3] shows that at the present time scholarships and loan funds have been established in forty-eight medical colleges for the use of students who are without means otherwise to procure a medical education Altogether 296 free scholarships are now available, 116 more than were reported a year ago The increase in the number of scholarships, therefore, has been far greater than the increase in tuition fees It is a fact that students with limited finances frequently do better both in their studies and in their subsequent practice than some who have had ample funds at their disposal In this democracy the way must be kept open so that every deserving student, regardless of his financial condition, may find a ready and welcome entry to the practice of medicine

THE FALLIBILITY OF DRUG THERAPY IN TEXTBOOKS

Until very recently, we were compelled to acknowledge that little if any progress was being made in internal medicine so far as drug therapy was concerned Everybody knows of the progress made in other branches—in bacteriology, in pathology, in biologic chemistry, in surgery, in etiology and in the application of technical methods to diagnosis Recently, however, pharmacologic research and the application of scientific methods in the study of the physiologic action of drugs are resulting in definite, positive progress An important lesson, incidentally learned through this scientific investigation, is the fallibility of the drug therapy described in textbooks The explanation is, of course, that many of these textbooks are mere compilations containing false statements, unproved theories, and unverified clinical evidence representing the guesswork of ancient uncritical observers Many drugs have been, and still are, vaunted in textbooks as valuable in a variety of conditions, whereas scientific investigation and controlled clinical observation have proved them to be totally worthless, others are proving to be of value in an extremely limited number of conditions The sooner writers of textbooks realize this fact and enter into the spirit of the new era, the better for the public and for scientific medicine

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest, such as relate to society activities, new hospitals, education, public health, etc)

CALIFORNIA

New Attorney for the State Medical Board—John W Hart, Los Angeles, has succeeded Mr Ray Nimmo, resigned, as attorney for the State Medical Board

Personal—Dr Cornelius Van Zwaluwenburg, president of the Riverside Chamber of Commerce, fell down stairs at the Riverside City Hospital, fracturing his right femur——Dr William Palmer Lucas, San Francisco, professor of pediatrics in the University of California Medical School, has gone to Europe to aid in the organization of children's work for the American Commission for Relief in Belgium——Dr Hardolph Wasteneys has been appointed associate professor of pharmacology in the new department of biochemistry in the University of California Medical School

Medico-Military Preparedness—May 18, the scientific program of the Los Angeles County Medical Association was devoted to a symposium on "Military Medicine" Lieut-Col William E Purviance, M C, U S Army (retired), Los Angeles, delivered an address on "Medical-Military Preparedness", Lieut John J Kyle, M R C, U S Army, Los Angeles, major surgeon of the One Hundred and Sixtieth Indiana Infantry, U S V, during the war with Spain, spoke on "The Making of a Medical Officer", Maj Harlan Shoemaker, Los Angeles, formerly M C, N G Pa, now captain, M C, N G Calif, and first lieutenant, M R. C, U S Army, read a paper on "The Medical Corps of Our Army as a Career—With Some Recent Scientific Achievements by the Regular Medical Corps," and Maj Charles W Decker, M C, N G Calif, first lieutenant, M R C, U S Army, discussed "Sanitary Organization and Military Administration."

COLORADO

Schussler, Orland, Ill, Dr Effie L Lobdell, Chicago, Mrs John F Brownell, Franklin Parish, La, Mr Daniel Coit Campbell, Chesterfield, S C, Mr W G White, Chesterfield, S C., Mr W A Watson, Chesterfield, S C, Mr R T McCreight, Ruby, S C, Mr Spencer Sellers, Ruby, S C, Dr W J Perry, Chesterfield, S C, Dr C A Glover, Chesterfield, S C, Mr Clarence L Goldstein, Oakdale, Tenn, Mr W J Johnson, Oakdale, Tenn, Mr J H Lynch, Oakdale, Tenn, Mr H J Ellis, Ashford, Ala, Mr G M Gresham, Cottonwood, Ala, Mr H B Williams, Ashford, Ala, Mr Dow Harrelson Charleston, S C, Mr William Marbury, Sylacauga, Ala, Mrs E E Gilliand, Kellyton, Ala, Mr Arthur Hill Grimmer, Chicago, Mr Joseph A. Dickson, Heston City, Tenn, Mr Newt C Gailbraith, Sunny Point, Tenn, Mr L V McMurray Sardis, Tenn, Mr J W Hassel, Sardis, Tenn, Mr A S Montgomery, Sardis, Tenn, Mr J W Knight, Inverness, Fla, and Mr O A Pierce, Tuca, Fla Besides the above testimony, depositions were read

Conference of Boards of Health—The thirty-first annual meeting of the Conference of State and Provincial Boards of Health of North America was held in Washington, D C, May 16, following the Conference of State and Territorial Health Authorities with the United States Public Health Service While a certain overlapping in the programs and proceedings of these two conferences seems unavoidable, the fact that the Conference of State and Provincial Boards is essentially an international body has in the past given its proceedings a color not obtainable in the strictly official conference of United States health authorities with the United States Public Health Service At the recent conference, presumably owing to the unusual conditions now prevailing in Canada as a result of the war, but one Canadian province was represented

In his presidential address Dr Ennion G Williams Commissioner of Health of Virginia urged the importance of coming to some understanding as to the exact limits of the work that is to be undertaken as public health work He pointed out the predominant importance of the educational activities of public health agencies at the present time and urged their enlargement and continuance until they are taken up in a satisfactory manner by educational authorities and by private educational institutions The address suggested the advisability of cooperation between federal and state authorities or between groups of state and territorial sanitary authorities in intensive campaigns to be carried on in the several jurisdictions simultaneously against certain definite diseases in order that the efforts of any one state might not be rendered unsuccessful or diminished in their effectiveness by the introduction of disease from beyond its borders The use of salvarsan as a public health agency was urged by Dr Allan J McLaughlin, Commissioner of Health of Massachusetts who pointed out that if this remedy or some efficient substitute for it could be made generally available to all persons suffering from syphilis without reference to their ability to pay for the drug its more general use would limit the duration of the infective period of the disease in many cases in which this cannot now be accomplished and would thus tend to diminish the number of infections Massachusetts has already taken action toward this end

Officers were elected for the coming year as follows president, Dr Thomas D Tuttle, Seattle, commissioner state board of health, Washington, D C, vice president, Dr Samuel L Jepson, commissioner of health of West Virginia, and secretary, Dr Eugene R Kelley, chief of the division of communicable diseases, state department of health, Massachusetts

Conference of Health Authorities With the Public Health Service—The Fourteenth Annual Conference of State and Territorial Health Authorities with the United States Public Health Service was held in Washington, D C, May 13 and 15 Twenty-nine states and territories and the District of Columbia were represented

With a view to increased efficiency and economy of work in the field of rural sanitation and to prevent overlapping of various fields of sanitary effort the conference recommended that the surgeon general appoint a committee to define the limits of the activities that might properly be regarded as coming within the purview of the work of a bureau on rural sanitation and to define methods and standards for work in that field In order to simplify and to make uniform administrative measures pertaining to the sanitation of travel the conference recommended the appointment of a committee to study the regulations of the various states and territories for the sanitary control of travel and of common carriers and the federal interstate regulations pertaining to the same matter, and to report at the next annual conference a draft of standard regulations In so far as uniformity can be brought about in interstate and intrastate regulations, the duties of common carriers, travelers and shippers will be simplified, and the enforcement of such regulations by the authorities charged with such work will be facilitated The conference went on record as believing in the present feasibility of establishing a morbidity registration area for reportable diseases, analogous to the registration areas established by the Bureau of the Census for births and deaths, and requested that the surgeon general of the Public Health Service determine the practicability of this project and to fix standards for the admission of states and cities to such a registration area if established The appointment of a committee was recommended to formulate standard methods of recording public health data with particular reference to cost accounting by public health agencies, and of a committee to report on feasible methods of increasing the efficiency and extending the influence of future conferences As a public health measure adopted to prevent and cure pellagra, the conference endorsed the use of a properly balanced diet as the only method now known to be effective The sanitation of schools and the protection of the health of schoolchildren are, according to a resolution adopted by the conference, proper functions of health authorities rather than of educational authorities, but the latter should cooperate in the planning and execution of such work Health insurance received the formal endorsement of the conference in a resolution declaring it possible, in the opinion of the conference, for health insurance operated by governmental systems to improve the economic status, efficiency and health of individuals through better treatment of the sick, and to make disease prevention by communities, states and the nation more efficient than at present Members of the conference were urged to impress on those planning legislation looking toward the establishment of health insurance to incorporate in such legislation provisions to establish effective and close cooperation between the officials in charge of the administration of health insurance and the health officials of local, state and national government.

FOREIGN

Institute for Tropical Medicine at Granada —Dr F F Martinez, who has published several works on tropical medicine, has been appointed director of the newly organized Instituto de Medicina Tropical y Mediterranea at Granada, Spain

Physician Temporary Governor of German Province — Dr Max Bierfreund was appointed by the military authorities governor of Insterburg, his home at the time of the Russian invasion of eastern Prussia Insterburg is not far from Konigsberg threatened by the Russians He has recently published a book on his experiences, *Meine Erlebnisse als Gouverneur von Insterburg,* which has attracted considerable attention, according to our Dutch exchange

Deaths in the Profession Abroad —E Jungfleisch, professor of organic chemistry at the College de France at Paris, with a chair also at the Conservatoire des Arts et Metiers and for thirty years at the Ecole de Pharmacie ——M Straub, professor of ophthalmology at the University of Amsterdam, aged 57 He was editor of the *Nederlandsch Tijdschrift voor Geneeskunde* for the eight years ending with 1903, and was secretary of the international ophthalmologic congress at Utrecht in 1899, and has published numerous works on ophthalmology ——T Guilloz, professor of radiology at the University of Nancy, recently died a martyr to his study of the Roentgen rays, aged 48 He has contributed much to their technic and clinical application, and our Paris exchanges relate that although suffering since 1900 he organized the Roentgen-ray service for a large division of the army, and to the very last utilized his sleepless nights in promoting the welfare of the wounded and in scientific research

PARIS LETTER

Paris, April 20, 1916

The War

BLOOD VESSEL SUTURE IN WAR SURGERY

Functional troubles from alteration in the vessels are particularly frequent after traumatisms of war Dr Victor Pauchet of Amiens remarked before the Societe de chirurgie de Paris that often it is possible to make an end-to-end or lateral suture even if the vessels are separated, for the arteries are elastic The reason that the surgeon does not do so is that the procedure is delicate and tedious, and requires a scrupulous technic and a special instrumental equipment If the continuity of the vessels is reestablished, circulatory troubles are less frequent and gangrene rarer than after obliteration of the vessel This is ample argument in favor of suture, which is to be advised whenever the arterial walls and the neighboring tissues are in such condition as to permit it Pauchet showed before the Societe de chirurgie two cases of popliteal aneurysm, one arterial, the other arteriovenous, both treated by suture with recovery

Dr Souligoux of Paris does not agree with Pauchet He thinks that there are few indications for blood-vessel suture in the cases seen in the base hospitals

At the Reunion medicale de la IV-e armee, Dr Sejournet emphasized the advantages of suture for wounds of veins For wounds of large veins he rejects massive compression because it does not insure drainage and favors infection while not avoiding the risks of secondary hemorrhage His preference is for lateral suture, which decreases the caliber of the veins but slightly and reestablishes the circulation This operation demands the nicest care in order not to dislodge a clot of recent formation which may partly obliterate the orifice

Dr Brechot of Paris does not agree with Sejournet He believes that in military surgery suture of the large veins of the neck and limbs should be prohibited Under peace conditions in aseptic cases with a special technic it may produce a good functional result and the caliber of the vein may remain permeable

Dr Potherat of Paris also believes that while, in civil life, suture is advisable in certain cases of lateral wounds, especially wounds made by sharp weapons, this is not the case in military surgery While simultaneous ligature of the principal artery and of its collateral vein is more likely to produce gangrene of the limb than ligature of the artery alone, this does not mean that ligature of the vein alone will have the same consequences

Dr Schwartz of the Faculte de medecine de Paris also thinks that ligature should be preferred to suture for wounds of the veins

In answer to these objections, Dr Sejournet explained that he had in mind only partial wounds of the large veins He did not minimize the indications for ligature, but he did not believe it to be so benign or free from danger to the venous circulation Moreover, nothing in his three cases gives reason to suppose that suture was followed by the formation of an obliterating clot. No disturbance of the venous circulation occurred

RESECTION OF THE ELBOW FOR ARTHRITIS CAUSED BY A PROJECTILE

To moderate the enthusiasm of advocates of immediate or very early resection of the elbow in arthritis produced by a wound from a projectile Dr Begouin of the Faculte de medecine de Bordeaux reported before the Societe de chirurgie de Paris the results of seventeen resections of this class performed by various surgeons, which he had occasion to observe some time after the operation These results were truly deplorable In fifteen of the seventeen cases the forearm swung inertly like a flail, even during muscular efforts In the two other cases the arm was better, but quite unserviceable, neither patient could carry a spoon to his mouth, write or button his clothing Begouin believes that the good results reported hitherto were obtained, not in large series, but in isolated cases, in the hands of surgeons who are specially familiar with resection and who had sufficient time —rare now in these times of excessive overwork—to oversee the details of the necesary after-care He fears that most of the results obtained by average surgeons can scarcely be better than those reported by him If this be so, there should be no delay in recognizing that the functional results of resection of the elbow performed at this secondary period are clearly inferior to those obtained by permitting ankylosis in good position During this secondary period of the course of cases of arthritis, comprised between the third or fourth day after the patient's arrival in the base hospital and the second or third month, resection should be performed only exceptionally, if the extent of the lesions and the severity of symptoms make it necessary for saving life or limb Such cases, however, are rare, and Begouin has been impressed by the relative benignity of the cases of arthritis of the elbow that he has seen Under treatment by liberal incision, lavage, especially with hydrogen peroxid removal of fragments and careful attention, with curettage finally in some cases, uncomplicated recovery has occurred in all cases, with ankylosis as a final result much superior to the swinging forearm mentioned previously

Professor Quenu believes that Begouin's warning is timely but should not be exaggerated, especially since the swinging forearm is not an incurable infirmity, but may be corrected without great trouble The question of the superiority of ankylosis over the mobility given by resection is another matter, the cases should be classified according to the patient's occupational requirements as to whether strength is needed rather than mobility or vice versa.

Dr Routier of Paris agrees with Quenu, although he himself has never performed resection of the elbow during suppuration. It should not be forgotten, moreover, that the swinging forearm bears at its end a hand, which is worth more than the best orthopedic apparatus furnished after amputation.

Dr Broca of the Faculte de medecine de Paris believes the results of arthrotomy with removal of fragments to be better than those of resection in traumatic arthritis of the elbow. He agrees with Begouin that generalization should not be too sweeping in these cases.

Professor Hartmann does not believe that systematic resection is indicated in suppurating arthritis of the elbow. His patients have recovered under treatment by drainage combined with removal of fragments and immobilization of the elbow, which is always possible, no matter what the extent of the wounds, with a plaster splint. The reason that good results have not always been obtained in suppurative arthritis of the elbow is that immobilization has not been combined with drainage, this immobilization is a necessary feature. It is true that recovery under such conditions leaves the patient with an ankylosis, but if the arm is in good position it gives the patient a firm elbow which is sufficient for the requirements of many callings, even that of a soldier. If the patient later in civil life, desires to take up a vocation requiring a movable elbow rather than strength, there is nothing to prevent a secondary orthopedic resection.

TREATMENT OF SUPPURATIVE ARTHRITIS RESULTING FROM FIREARM WOUNDS

The Societe de chirurgie de Paris continuing the discussion on resections in arthritis, Dr Auvray of the Faculte de medecine de Paris brings forward statistics of twenty-eight cases of suppurative arthritis of the elbow which he has had occasion to treat since the commencement of the war. He has often sought to obtain, by resection, a better drainage of the articulation than could be obtained by arthrotomy alone in some cases. He feels sure that he has been able, by resection, to save many limbs and several lives.

Professor Kirmission is of the opinion that early resections for extensive crushing fractures of a joint ought to be practiced only as operations of necessity in order to search in all the remote corners for bony fragments or separated portions of soft tissues. Numerous wounded men have been rendered cripples, with dangling limbs, forever dependent on orthopedic apparatus, because of such imperfectly performed operations. For such persons an ankylosis in good position would have been preferable. Secondary resections are done to give a free exposure for the purpose of combating the suppurating arthritis and the grave septicemia which the latter often provokes. But, here, again, antiseptic dressings properly applied and especially, rare (sic) dressings, free exposure and thorough drainage suffice in the majority of cases to effect a cure. For his own part, while he has had a large number of crushing articular fractures and cases of suppurating arthritis of the elbow, of the shoulder and of the knee, Kirmisson has been able to obtain cures though he has never performed resection in these cases. Late or orthopedic resections in war surgery have all the value that they have in civil surgery, and are capable of yielding the best results. It is especially at the elbow that orthopedic resection is most useful and most frequently indicated. Dr Picqué, surgeon of the hospitals of Paris, shows by his personal experience the necessity and advantages of immediate treatment of joint wounds in the ambulances at the front, in the same way as injuries of the long bones, of the skull, of the chest and of the abdomen. This treatment should, above all, be prophylactic and conservative. Arthrotomy is the first step. By it access to the joint is obtained and the opening must be large enough to permit of exploration. In the rare cases of simple synovial lesions it will suffice and its nonsuccess in other cases is sufficiently explained by the coexisting bony lesions. Arthrotomy in these cases is but the prelude to an operation on the bone. What form should this latter take? The surgeons of Lyons are frankly in favor of typical resections. Their colleagues of Paris more generally prefer atypical resections. The latter may be anything between a simple cleaning out and an extended resection of the whole of the articular extremity of the bone, determined naturally in each case by the extent of damage. Conservative treatment may also be attempted by such an atypical resection not only in the case of a wounded man who arrives at the ambulance a few hours after the receipt of his wound but also when he comes under observation during the first days, though already suffering from a suppurating arthritis or a threatening septicemia, but in this case the vigilance of the surgeon must always be maintained, in order to detect in the course of frequent dressings the earliest indications for a more radical intervention. Conservative policy becomes dangerous as soon as the surgeon relaxes his guard. Indeed, in many cases, it should be but the prelude for a more energetic attack on the condition, in the course of which total extensive resection, supplemented by the usual counteropenings for drainage, may be practiced in accordance with the well-established rules of operative technic. Finally, when with judicious local treatment and the utmost subsequent care, the infection fails to be localized, one must not await septicemia before amputating. Partial resection, total resection and amputation must be substituted one for the other, successively, to meet the dangers, respectively, of arthritis, of septicemia and of death.

MORE RATIONAL UTILIZATION OF THE SERVICES OF MEDICAL STUDENTS

The minister of war lately received a delegation from the medical group in parliament, which demanded better employment for medical students, who ought to be used as technical assistants and not as mere nurses. The delegation also demanded that the students should be grouped under the name of *élèves aspirants du Service de Santé* near a hospital where they should receive special instruction and, after examination, the title of *aspirants*.

THE EVACUATION OF HOSPITALS NOW LODGED IN HIGH SCHOOLS

The Association des parents d'eleves des lycees de Paris has just passed a resolution demanding the removal from school buildings of the military hospitals that might be lodged in other convenient buildings. The resolution mentions the pedagogic, hygienic and moral disadvantages, the dangers of contagion, the crowding of classes, etc, which result from the prolonged lodgment of hospitals in high school buildings.

Social Hygiene Dispensaries

A law has just been passed establishing public dispensaries for social hygiene and for antituberculosis compaigns to be carried on by means of education, and advice on prophylaxis and hygiene, as well as by assuring institutional care to those ill with infectious diseases. Further when necessary, the dispensaries will place their services at the disposition of the public for disinfection of clothes and other materials as well as dwelling houses and other places which have been infected. For the indigent sick they arrange free consultations and distribution of medicine. They may place their services at the disposal of mutual benefit societies and charitable organizations.

LONDON LETTER

London May 8, 1916

The War

THE NEW BRITISH HELMET AS A PROTECTION AGAINST HEAD WOUNDS

On the Allied side the French were the first to adopt a steel helmet in consequence of the large number of wounds of the head. The British then devised a helmet which has not the surprising lightness of the French but it is considered to be better designed to meet its purpose. It has a wide downward sloping brim, and thus protects the side and back of the neck and the temples and upper part of the face as well as the top and sides of the head. This breadth of brim makes the crown look shallower than that of the French helmet, but a more real difference is that the British helmet has a smooth round top, while the crown of the French presents a prominent ridge tapering centrally backward. This ridge was originally intended to strengthen the helmet, but being hollow and open at one end it also provides a means of ventilating its interior. In addition it adds to the head dress a style that the English helmet lacks. But it is open to question whether these advantages are not outweighed by the fact that a fragment which would glance harmlessly off the smooth round British crown might be stopped by this ridge on the French helmet, and inflict on the wearer a stunning jar if not worse. The British helmet stands away from the head about one third inch all round the weight being borne by a padded leather band fixed to the inner side of the surrounding steel by a series of india rubbia buffers each about the thickness of a lead pencil and about 1 inch long. This detail constitutes perhaps the most important difference between the British and French helmets The buffers are capable of diffusing and neutralizing the force of a blow which, falling on the closely fitting French helmet, would be conducted direct to the brainpan The heaviness of the British helmet is a drawback Possibly its protective effect would be increased by lowering the brim still further so as to guard against bomb fragments or other missiles rising upward from a point within a yard or two of the wearer The experience of recent wars shows head wounds amounting to 15 per cent , but recent data of the present trench warfare show a percentage of about 25 The introduction of helmets was followed by a considerable reduction The cases at one clearing station were analyzed, and it was found that penetrating gunshot wounds of the head formed only 0 5 per cent, while the total fractures of the skull were under 1 per cent Moreover, there was the direct evidence of the helmets of men who had been struck on the head by missiles of various kinds, but who sustained no injury more serious than a scalp wound Indeed, some men whose helmets had been dented or pierced or broken were not even aware they had been struck Though the helmets were by no means bullet proof they commonly offered such resistance that a missile which penetrated them lost most of its force

MILITARY ORTHOPEDICS

One of the new features of army medical organization is the extent to which the War Office has used specialists of all kinds Our leading orthopedic surgeon, Mr Robert Jones has been appointed inspector of military orthopedics He has been surgeon to the military orthopedic center at Alder Hey Military Hospital, near Liverpool, since its establishment He is also a member of the staff of the hospital at Roehampton for men who have lost a limb in the war This is a special hospital for men who have undergone amputation of a limb Accommodation is provided for 300 The men are retained until the artificial limbs they need have been made and adjusted under the supervision of the experienced staff of orthopedic surgeons A hospital on similar lines is being established in Glasgow, where the same system of supervision and construction of artificial limbs on the spot will be followed Cases of this class are being reported at the rate of 300 a month In addition to the men who have undergone amputation there are among those returning from abroad to military hospitals at home many cases of injuries of limbs, especially of joints, varying in severity but all more or less interfering with the ability to work in civil life Recognition of the fact that these men can be greatly benefited by skilled orthopedic treatment begun as early as possible is shown by the appointment of an inspector of military orthopedics, who will exercise general supervision of the treatment of orthopedic cases in the various military hospitals and sections of hospitals, and arrange for the transfer of suitable cases to selected centers of orthopedic treatment The types of cases which will come within the scope of the scheme are (1) derangements and disabilities of joints, including ankylosis, (2) malunited and ununited fractures, (3) injuries to ligaments, muscles and tendons, (4) cases requiring tendon transplantation or other measures for irreparable destruction of nerves, (5) nerve injuries by fractures or stiffness of joints, (6) certain complicated gunshot injuries to joints, and (7) cases requiring surgical appliances The Hammersmith Military Hospital (in London) will be the first military orthopedic hospital to be organized under the supervision of the inspector of military orthopedics The buildings consist of the Hammersmith Infirmary and Workhouse, and will hold a total of about 800 men In addition to the ordinary surgical orthopedic service, there will be departments for treatment by massage and mechanotherapeutics, electric treatment, and radiant heat, whirlpool and other forms of baths, each in its own quarters There will also be a large and well fitted gymnasium The workshops of the buildings are large, and it is hoped to be able to fit them in such a way that all splints, surgical appliances, special boots and instruments, etc, may be made on the premises Special accommodation is to be made for plaster-of-Paris work, including the taking of plaster-of-Paris casts The staff of the hospital, apart from the administrative officers, will consist in the first place of four surgeons, a consulting neurologist, physicians in charge of the massage, electric and balneologic departments, Roentgen-ray specialist, anesthetist, gymnastic instructor, and four resident medical officers

THE SUPPLY OF MEDICAL OFFICERS FOR THE ARMY AND NAVY

A considerable number of physicians are still required for service in the army medical corps The development of military operations has caused a large proportion of the medical officers who have hitherto been serving in this country to be detailed for service abroad, and it is essential that there should be others ready to meet future demands This request for officers has come before the enrolment scheme (described in previous letters to The Journal) of the Central Medical War Committee has been completed The committee is therefore compelled to ask for volunteers from among both the enrolled and the unenrolled The present condition is well described by Sir Clifford Allbutt and Sir William Osler in a letter to the *Lancet* During the next few weeks the course of events seems certain to lead to renewed fighting, to many casualties, and to a call for more and more physicians to tend the sick and wounded The supply could be met—as, if other methods fail, doubtless it would be met—by conscripting physicians, but some time ago the War Office recognized that a scheme of voluntary enrolment could be made to give them what they wanted and in a better way The working of the scheme was entrusted in England and Wales to the Central Medical War Committee, a committee representing the profession at large and the several medical corporations and schools, and in close touch with the insurance commission and the great government departments which employ physicians This scheme of voluntary enrolment, as contrasted with conscription, appears to present certain great advantages, in which both the community and the physician share In any circumstances some physicians must go, and some be kept at home, but whereas with conscription the task of selection might fall into the hands of local lay tribunals, the voluntary scheme provides that in each district it falls to a local committee of physicians whose knowledge of the profession and of local conditions enables them to form a better judgment both of the needs of the civil community and the difficulties of the individual physician This scheme has been framed to secure also a due rotation of work and sacrifice, so that when the volunteer has completed the year of service for which he signs, he is free to return home, his place in the army being taken by another, an arrangement fairer to himself and better for his civil patients than indiscriminate compulsion Now the success of the scheme obviously depends on the number of enrolments If the response is meager the army medical department will be starved, or rather conscription must come Moreover, the correlative provision for the civil population and the fair distribution of sacrifice will be imperiled It is true that the response so far has been fair, but with the spring campaign on us, the need for more men, and yet more, is so pressing that there is considerable anxiety even in respect of the immediate future The scheme can work well only if all, or practically all, physicians of suitable age enroll themselves However, not unnaturally, some are hesitating to enroll lest a lack of enrolments should expose them unfairly to be summoned This cannot, in any case, happen, since the committee has decided that no calls shall be made until 75 per cent are enrolled Every physician of military age is therefore urged to enroll

Marriages

John Moore Conway, M D, Pittsburgh, to Miss Theresa Straitiff of McCalmont township, Jefferson County, Pa, recently

Walter H Parcels, M D, Lewistown, Pa, to Miss Mary B Cummings of Readsville, Pa, at Atlantic City, N J, May 11

Herman H Dight, M D, Titusville, Pa, to Miss Lucille Walker of Emlenton, Pa, at Brookville, Pa, May 4

Carl Schumann, M D, Greene, N Y, to Miss Alice C Selle of Akron, O, at Warrensville, O, May 17

Henry Barber Richardson, M D, Boston, to Miss Margaret Carpenter of New York City, May 2

Nicholas August James, M D, to Miss Mabel Elisbeth Becker, both of Tell City, Ind, recently

Russell Bower Lynn, M D, Elmira, N Y., to Miss Ethel Isabell Raul of Easton, Pa, May 17

Homer P Yeater, M D, Maysville, Mo, to Mrs Essie Welsh of St Joseph, Mo, April 24

Howard Elmer Campbell, M D., Anita, Ia., to Miss Anna Laura Smith of Ames, Ia, May 10

Arthur Raymond Moon, M D, to Miss Beatrice Clark Jackson, both of Detroit, May 8

Deaths

William W Reed, M D, Jefferson, Wis , College of Physicians and Surgeons, Keokuk, Ia , 1863, aged 91, for many years a Fellow of the American Medical Association, a member of the State Medical Society of Wisconsin, for four years a member of the General Assembly, eight years state senator, twelve years mayor of Jefferson, health officer of Jefferson and Jefferson County for about thirty-six years, and for twenty years a member of the State Board of Charities, an active practitioner for sixty-six years, died at his home, May 10 In 1909 the Jefferson County Medical Society gave a banquet in honor of Dr Reed to celebrate the sixtieth anniversary of his arrival in Jefferson and on this occasion presented Dr Reed with a silver loving cup

John D Zwetsch, M D, Gowanda, N Y , Cleveland University of Medicine and Surgery, 1882, aged 57, a member of the Medical Society of the State of New York, formerly a Fellow of the American Medical Association, local surgeon at Gowanda for the Erie Railroad, a member of the consulting staff of the Gowanda State Hospital, and a member of the International Association of Railway Surgeons, was instantly killed by the overturning of his automobile near the Gowanda State Hospital, May 6

Edward Leaming, M D, New York City, College of Physicians and Surgeons in the City of New York 1892, aged 54, a Fellow of the American Medical Association and Royal Photographic Society, professor of photomicrography in the department of pathology of his alma mater and the Rockefeller Institute, president of the Roentgen Society of New York, visiting roentgenologist to Roosevelt Hospital, an expert in roentgenology and photography, died at his home, May 11

James Ross, M D, Halifax, N S , McGill University, Montreal, 1890, aged 48, lieutenant colonel C A M C , for many years editor of the *Maritime Medical News* which was amalgamated with the *Canadian Medical Association Journal*, extra-mural lecturer on dermatology and genito-urinary diseases in Halifax Medical College, surgeon to the Dermatological Department of Victoria General Hospital, died suddenly, May 8

James Robert Jones, M D., Winnipeg, Man , University of Toronto, Ont. 1878, L R. C P, London, aged 67, professor of theory and practice of medicine in Manitoba Medical College, Winnipeg, physician to the Winnipeg General Hospital and president of the College of Physicians and Surgeons of Manitoba, died in St Paul, Minn, January 11, from cerebral hemorrhage, secondary to arteriosclerosis

Victor Alexander Bles, M D, Denver, University of Colorado, Boulder, 1895, aged 43, a Fellow of the American Medical Association, formerly assistant to the chair of neurology of St Louis University and assistant neurologist to St John's Hospital, later a member of the staff of the Elgin State Hospital, died in St Luke's Hospital, Denver, May 9, from tuberculosis

Joseph S Baldwin, M D., Freeland, Md , University of Maryland, Baltimore, 1874, aged 69, sanitary officer of the Sixth District of Baltimore County, for many years a practitioner of Elko, Mo , died, May 6 in the James Buchanan Brady Institute, Johns Hopkins Hospital Baltimore, from malignant disease, for which operation had been performed seven days before

Abner Howard Powers, M D, Boston, Boston University School of Medicine, 1885, aged 60, professor of surgery in his alma mater, surgeon in chief and dermatologist to the Homeopathic Medical Dispensary and medical director of the Medical Mission Dispensary Boston, died at his home, May 13, from injuries received in an automobile collision a month before

William Rufus Hedgpeth, M D., Paso Robles Calif Missouri Medical College, St Louis, 1891, aged 60, a Fellow of the American Medical Association, formerly local surgeon to the Southern Pacific System, a well known specialist on diseases of the eye ear nose and throat, died at his home, April 22, from angina pectoris

N Noble Vance, M.D, Bement, Ill , Medical College of Ohio, Cincinnati, 1868, aged 71, formerly a member of the Illinois State Medical Society and one of the organizers of the National Association of Railway Surgeons, a veteran of the Civil War, for more than forty years a practitioner of Bement, died at his home May 10 from cerebral hemorrhage

William H Sparling, M D, Moweaqua, Ill , Detroit College of Medicine and Surgery, 1872, aged 66, a Fellow of the American Medical Association, and formerly president of the Central Illinois District Medical Society, local surgeon to the Illinois Central system, a member of the National Association of Railway Surgeons, died at his home, April 3

Auren Alfred Stafford, M D, Alameda, Calif , Cooper Medical College, San Francisco, 1896, aged 46, a Fellow of the American Medical Association, formerly president of the Alameda Board of Health, physician to the German Old Peoples Home of California, died at his home, May 7

Willis Edward Crane, M D, Hamill, S D , Rush Medical College 1879, aged 59, formerly a member of the South Dakota State Medical Association, died at his home, April 6, from the effects of a gunshot wound of the head, self-inflicted, it is believed, with suicidal intent

Oliver Henry McMichael, M D, Minneapolis, University of Michigan, Ann Arbor, 1871, aged 70, a Fellow of the American Medical Association, a practitioner of Vernon Center Minn for forty-three years, died at the home of his daughter in Minneapolis, May 10

Herbert Lucius Hulburd, M D, Morris, Minn , Long Island College Hospital, Brooklyn, 1875, aged 64, a Fellow of the American Medical Association, physician to the Government Indian School and Hospital, Morris, Minn , died at his home May 13, from septicemia

John Robert Everitt, M D, Jersey City, N J , Long Island College Hospital, Brooklyn, 1872, aged 69, surgeon to the Jersey City and Emergency hospitals, for thirty years a member of the Jersey City Board of Health, died at his home May 15, from diabetes

James Scott, M D., Portland Ore , State University of Iowa, Iowa City, 1873, aged 72, for many years a practitioner of Grant, Ia , but for the last four years a resident of Portland, Ore , died suddenly in a bank in Albany, Ore, May 10 from heart disease

Francis William Campbell, M.D, Brooklyn, College of Physicians and Surgeons in the City of New York, 1909, aged 31, visiting anesthetist to St Catherine's Hospital, Brooklyn, and gynecologist to St Catherine's Dispensary, died at his home, May 9

Charles S Meahl, M D, Buffalo, N Y , University of Buffalo, 1890, aged 47, city diagnostician of Buffalo and for many years a city examiner in lunacy, died at his home April 17 from cirrhosis of the liver associated with pulmonary tuberculosis

Norman James Lang Yellowlees, M D, Toronto, Ont , University of Toronto, 1909, aged 29, captain in the Canadian Army Medical Corps and on duty with the University of Toronto Base Hospital, is reported to have been accidentally drowned at Saloniki

Manfred Robert Martin, M D, Vernal, Utah, College of Physicians and Surgeons, Chicago, 1904, aged 36, a member of the Utah State Medical Association, died in the Garfield Park Hospital, Chicago, May 8, from heart disease associated with diabetes

Willis W Barnes, Louisville, Ky , (license Kentucky 1903) aged 63, a practitioner since 1882, also a dentist and professor of dental surgery in the University of Kentucky Medical Department, died at his home, March 1, from endocarditis

Isaac Newton Power, M D, Cle Elum Wash , Willamette University, Salem Ore 1877, aged 64, formerly a Fellow of the American Medical Association, a member of the local board of education, died at his home, May 6, from pneumonia

Albert Wickman, M D, Newark, N J , New York University New York City, 1894, aged 48, a Fellow of the American Medical Association, physician to the Newark General Hospital, died suddenly at his home, May 13, from heart disease

Edward A Fox, M D., Cincinnati, Medical College of Ohio Cincinnati 1905, aged 34 local surgeon to the Big Four System, physician to the Hamilton County Infirmary in 1909 and 1910, died at the Bethesda Hospital, Cincinnati, May 7

Vincent West McNeill, M D, Prospect, Ohio, Starling Medical College, Columbus, 1892 aged 45 also a graduate in pharmacy, formerly a member of the Ohio State Medical Association died at his home May 12 from uremia

Johnson W Pettijohn, M D, Hoyt Kan , Georgetown University, Washington D C., 1864, aged 82, a member of the Kansas Medical Society and a pioneer practitioner of Hoyt, died at his home near that place, May 14

Robert G Schaller, M D, Alton, Ill , University of Munich, Bavaria, 1889, aged 66, formerly a Fellow of the American Medical Association, a member of the Illinois State Medical Society, died suddenly at his home, May 11

James Edwin Weller, M D, Richmond, Ind , Jefferson Medical College, 1901, aged 41, a member of the Indiana State Medical Association, a surgeon of volunteers during the war with Spain, died at his home, May 10

Arad A Simons, M D, Cloverport, Ky , University of Louisville, Ky, 1892, aged 57, a Fellow of the American Medical Association, surgeon to the Henderson and St Louis Railroad, died at his home, May 7

Henry L Donsife, M D, Frederick City, Md , University of Maryland, Baltimore, 1864, aged 73, died in the Montevue Hospital, Frederick, May 10, from shock from scalds believed to have been accidentally received

John F Hanifin, M D, Holyoke, Mass , College of Physicians and Surgeons, Baltimore, 1911, aged 30, a member of the Massachusetts Medical Society, died in Saranac Lake, N Y, May 7, from tuberculosis

Stephen Elvaro Webber, M D, Calais, Me , Harvard Medical School, 1894, aged 55, a Fellow of the American Medical Association, died at his home, January 11, from chronic interstitial nephritis

Pierre Valance Roudiez, Denver, (license Colorado, 10-year clause, January, 1891), aged 81, surgeon of volunteers during the Civil War, died at his home, May 13, from pneumonia

James D Peters, M D, Renton, Wash , Eclectic Medical Institute, Cincinnati, 1868, aged 80, *for more than forty* years a practitioner of Grand Rapids, died at his home, April 13

Marcus Barclay Dwight, M D, Philadelphia, Jefferson Medical College, 1875, aged 64, a member of the Medical Society of the State of Pennsylvania, died at his home, May 8

William Merrill Bullard, M D, Flatbush, Brooklyn, N Y , University of Gottingen, Germany, 1867, aged 74, died at the home of his daughter in Brooklyn, May 12, from heart disease

Daniel E Evans, M D, Nanticoke, Pa , Baltimore University, 1892, aged 66, formerly a member of the Medical Society of the State of Pennsylvania, died recently at his home

Adam Ramsey Insley, Little Rock and Redfield, Ark , (license, Arkansas, 1903), aged 80, a veteran of the Civil War, died at his country home at Redfield, April 27

Samuel W Sigler, Warren, O , (license Ohio, 1899), aged 78, for more than fifty years a resident of Niles, O , died at his home in Warren, May 12, from uremia

Ludwell Yancy Browning, M D, Mays Lick, Ky , University of Pennsylvania, Philadelphia, 1866, aged 75, died at the home of his son near Elizaville, Ky, April 29

Joseph Rowe Webster, M D, North Lexington, Mass , Harvard Medical School, 1859, a member of the Massachusetts Medical Society, died at his home, May 9

Joseph N Charbonneau, M D, Worcester, Mass , Victoria University, Toronto, Ont, 1874, aged 65, died at his home, February 9, from valvular heart disease

William Henry Hoyt, M D, Wenham, Mass , New York University, New York City, 1886, aged 53, formerly of Sioux City, Ia , died at his home, May 3

Thomas S Gibson, M D, Alexandria, Va , University of Maryland, Baltimore, 1887, aged 56, died at his home from cerebral hemorrhage, April 26

Edward Milton Duff, M D, Hollidaysburg, Pa , University of Pittsburgh, 1892, aged 49, died in his office, May 4, from cerebral hemorrhage

John Huntington Van Kleeck, M D, Brooklyn, University of Buffalo, 1872, aged 67, died at his home, May 2, from pneumonia

George Washington Morgan, M D, Keener, Ala , University of Tennessee, Nashville, 1889, aged 60, died at his home, April 30

Isaac Cheney McCoy, M D, Fort Worth, Texas, Medical College of Georgia, Augusta, 1870, died at his home, April 29

Sheldon S Thayer, M D, Paisley, Ore , University of Oregon, Portland, 1899, died at his home, April 15

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

THE WINE OF CARDUI SUIT

(Continued from page 1649)

May 2, 1916, Morning

TESTIMONY OF DR NATHANIEL H ADAMS

Dr Nathaniel H Adams was called as a witness for the defendants

DIRECT EXAMINATION BY MR T J SCOFIELD

Dr Nathaniel H Adams testified that he resides in Oak Park, Ill, and has an office in Chicago He has been practicing medicine for twenty years He was graduated from the Northwestern University Medical College in 1896 He taught in the Illinois Medical College, the Chicago Dental College, and has attended patients in various hospitals for ten or fifteen years He taught chemistry for fourteen years and anatomy for three He is a member of the Chicago Medical Society, Illinois State Medical Society, the American Medical Association, and the Therapeutic Club He has done a general practice until within the past few years in which he has specialized somewhat in nervous diseases His treatment has been almost exclusively medical, and surgical cases have been referred elsewhere He knows of cnicus benedictus, but has never used it as a medicine He has had much experience with viburnum prunifolium, which he has used in various forms This experience has been that used alone it has no medical value If it is associated with an active drug it does not seem to add or detract from the potency of that drug

Q —In other words, if I understand you, you don't see any benefit—or have had no benefit from it either alone or in combination? *A* —Not from a drug standpoint, no sir

Q —Now, explain, doctor, what you mean by that, "not from a drug standpoint" *A* —I mean this, that I have been disappointed in the use of the drug for any therapeutic value I will say, however, that black haw has a clean bitter taste, and that this clean bitter taste with the slight flavoring of valerianic acid which is present, that it makes it a modifier of other tastes It is a drug that can be used in combination for the sake of its flavor and for the sake of adding a clean bitter to nauseous drugs, without having any medicinal value itself

The witness was then asked as to whether he had any opinion as to the value of a hypothetic medicine similar to that about which other witnesses were questioned

Q —Doctor, is there any ingredient as described, or ingredients, aside from the alcohol in this solution, that, in your opinion, would prevent the preparation being used in larger doses than in table spoonful doses *A* —In my opinion, this preparation contains a simple herb and a simple bark, which are not potent, which have no strong medicinal value and are not poisonous For that reason there is nothing in these two drugs to prevent the taking of this medicine in increasing doses for its alcoholic effect.

The witness was asked to distinguish between the cure and relief of various conditions, using as an example the treatment of a syphilitic ulcer of the cervix

Dr Adams then defined the word "tonic" He would not give a tonic for the cure of uterine prolapse, gonorrhea, uterine retroflexion, or an uterine inversion Tonics are rarely necessary in the treatment of such conditions

Ergot, pituitrin and hydrastis might be considered uterine tonics, he said He then described the way in which ergot acts as a uterine tonic

There was described to the witness an experiment similar to that performed by Dr J Clarence Webster, and he stated that a drug injected into the uterine wall which would produce no observable effect within ten minutes would be an inert drug It is not a uterine tonic or a uterine sedative

The witness then stated that the official fluidextract of ergot contains approximately 50 per cent of alcohol, and that amount is required to extract the virtues and preserve the preparation

Q —Doctor is there any disadvantage in using 50 per cent of alcohol as you find it in the fluidextract of ergot? *A* —Yes indeed there is

Q —What is it? *A* —Why the disadvantage—there are several disadvantages One is that ergot is nearly always used hypodermically and alcohol is an irritant in that use Then again, alcohol is a direct antagonist to the proper action of ergot. Alcohol tends to relax the vessels of the womb, and the action of ergot which is sought is to contract them The drug value of the fluid of ergot however is great enough to overcome the disadvantage of the presence of alcohol So if the fluidextract of ergot is used, you have to tolerate the bad effects of the alcohol for the good effects of the ergot

Q —Now doctor is that the reason that you use the ergotin instead of the fluidextract? *A* —Yes.

Q —In what dose when you use the fluidextract of ergot in what dose do you prescribe it? *A* —Ordinarily half a teaspoonful

Q —Under what conditions and under what circumstances do you prescribe the fluidextract of ergot? *A* —In the great majority of cases it is prescribed after childbirth to shut down the womb tighten the womb so that the blood will be squeezed out of it. It favors involution of the womb

Q —To what extent do you use it, under such circumstances how long? *A* —One dose as a rule following delivery

Q —Did you ever give it in a tablespoonful dose? *A* —Never in my life.

Q —Why? *A* —Why, that is tonic that is a poisonous dose, verging on a dangerous dose.

There was then read to the witness an advertisement from the New Orleans *Picayune* similar to those read to previous witnesses He stated that the hypothetic medicine corresponding to Wine of Cardui is not an absolutely natural vegetable food tonic for starved female functions The statements in the advertisement he considers absolutely false and vicious as leading to false hope

He described the way in which a bitter might be considered a tonic, but stated it could not be considered restorative He regards alcohol as an exhilarant and not a tonic He considers it absolutely detrimental in cases of inflammation of the pelvic organs of the female He considers that alcohol in the strength mentioned would brace up a patient suffering from some form of uterine displacement, the exact nature of which was not known, and that after the bracing effect there would be depression so that there would form a tendency toward increasing the frequency and the amount of the dose

Dr Adams then described the various reflex effects on the breasts of tumors of the womb, pregnancy, etc There was read to him from the Home Treatment of Female Diseases, 1912 Edition, an article under the general subject of the female breasts Dr Adams mentioned some of the various diseases of the reproductive organs in the pelvis as well as local conditions in the breasts which are evidence of disease It was his opinion that the use of this medicine would be to mask these conditions, not to relieve them

ALCOHOL AT PUBERTY

Dr Adams then described the condition of puberty He considers it a natural physiologic condition, and stated that a young girl in good health does not require any medicine at that time.

He was asked as to his opinion of the advice that the hypothetic medicine could never do anything but good if taken by a girl at puberty He stated that the recommendation is vicious and the advice is outrageous

CROSS-EXAMINATION BY MR HOUGH

Q —You are the Nathaniel H Adams who testified in the Jiroch case in Washington are you? *A* —I am the man who went to Washington for the attorney in that case to help him in regard to drug matters

Q —That was in April 1914? *A* —I think that is right.

Q —You testified in that case that treatment by mail was a proper legitimate way to treat didn't you? *Q* —No I testified as to the value of drugs and I testified that the drugs which they used were good drugs and all right and that if they were able to make a diagnosis by—in that manner that such drugs could be properly used.

Q —You testified that they would be entitled to form an opinion from the symptoms given by a patient by mail or over the telephone or any other way? *A* —I testified that that would be one of the methods by which they might make a diagnosis yes.

Q —You testified that viburnum prunifolium was a good remedy for uterine troubles did you not? *A* —No I don't remember that I think there was a preparation of Parke Davis tablets

Q —What was that answer? *A* —There was a preparation of Parke Davis tablets some of which contained viburnum prunifolium with other drugs. There was no viburnum prunifolium alone to my knowledge.

Q —Did you not testify that the fluidextract of viburnum prunifolium was recognized medicine for these conditions? *A* —The fluid extract?

Q —Yes *A* —Not to my knowledge, no sir It was a matter of tablets They were compound tablets, they were not viburnum alone

Q —What were they compounded with? *A* —I have forgotten

Q —You manufactured 'patent medicines" at one time yourself didn't you? *A* —I never manufactured "patent medicines," but I have manufactured proprietaries which were used by physicians.

Q —When was that? *A* —Well for many years I was in the drug business and I am a graduate of the College of Pharmacy and I was quite interested in the combination of various drugs and bringing out the best value of various drugs and I was also interested commercially in trying to make compounds which would be of use to physicians and compounds for which I could get a sale from which I could make a living by their real value and merit

Q —You manufactured some for home treatment, did you not? *A* —For home treatment?

Q —Yes A —Not myself, no, sir I may have done so in other drug stores where I was employed I may have manufactured them for druggists, but not for my own self

Q —You were being examined with reference to symptom blanks and advertisements of the Dr Jiroch Company were you not at that time? *A* —Well, in this hearing before the Master, it was a hearing—

Q —It was before the Attorney General and in the Postoffice Department in Washington, was it not? *A* —Yes that is right

Q —And was a proceeding for the alleged misuse of the mails? *A* —Well I went there to testify as to my knowledge of drugs

Q —You testified that that way of prescribing was legitimate and proper didn't you? *A* —No I testified that it was a method by which they could prescribe but I did not testify that it was the best method or a good method, or the method employed by me

Q —I am not asking you whether you said it was the best method I am asking you whether you said that it was a legitimate method? *A* —No I did not use that term

Q —What did you say about that? *A* —I said— I stated that a physician could give drugs for the treatment of disease when the symptoms were thoroughly described to him, sufficient for him to make a diagnosis and I stated that that might be applicable under certain circumstances I stated it was not my method and I did not consider it a good method, and it was not one in ordinary use. My object there was to testify as to the value of these drugs

Q —Did you state this

For instance it is possible and practicable for a doctor to treat many patients in the space of an hour or two who comes to his office and he will often accept their statements, and he may even accept their statements over the telephone For instance it is a common every day practice for some one to call up and say 'I have a cold or a headache or I am vomiting' or some thing like that tell us something to do' That is done over the telephone. That is not the ideal but it is the practical method A busy man will run into the office perhaps a lawyer and will say I have to go out on an argument this afternoon My head is throbbing give me something for it' We do not go over the man's body very much but give him something to meet the symptoms. That is ordinary practice and we could not be in business if we did not do that sort of thing Did you make that statement? *A* —Oh I think I did it sounds right

Q —Now on the question of cure you testified as to the meaning of that on that occasion didn't you, or do you recall. *A* —I do not recall that

Q —I will read to you from the report of your testimony In the general run of medical practice, in your treatment, when you speak of curing a disease what is the usual meaning or significance of that term? In general what is meant by that? And your answer Of course among physicians it would mean relief of the diseased condition For instance, if we cure a boil by lancing and leave a scar the word cure could only mean relief in the sense that we would have relieved the condition You stated that didn't you? *A* —I think that is very likely that physicians do not consider a cure to be a cure unless they relieve the disease unless the disease is cured

Q —You made that statement didn't you? *A* —I do not know whether I made that or not I think very likely I did

Q —In answer to Mr Dobbyns' question All I want to get at is what is generally understood by the treatment of disease? your answer was My only answer to that question is this that the object of the practice of medicine is to relieve human suffering and prolong human life and we cannot perfect the bunged up damaged machines that come to us We patch them up and try to relieve their symptoms and do to a certain extent You made that statement didn't you? *A* —Oh sure that is right

Q —And furthermore In the practice of medicine the important thing as I understand it from the standpoint of the physician is to relieve the symptoms and relieve the human suffering? And your answer is Yes sir *A* —You mean that was a question asked of me?

Q —That was a question asked of you and your reply is Yes *A* —Well that is my opinion that to relieve the human suffering is very very important if the disease cannot be relieved

Q —Well it was in that sense that you used the word cure was it not? *A* —I used the word cure only in the sense of curing the disease Otherwise it is relief or partial cure

Q —On that occasion you testified in that way didn't you that that was the sense in which you used the word cure? *A* —Th was not my conception, it was partial cure or relief of the symptoms We cannot always cure individuals, but we can often relieve them

Q—Well, then, you stop treating them, don't you? A—Why, no

Q—If they are relieved of the symptoms? A—Why, it depends upon whether—we do not if the symptoms recur If the symptoms recur they have to have further treatment

Q—Suppose they do not recur, suppose the symptoms do not recur? A—Well, if the disease—if the disease has abated so that it has become a condition which gives no active symptoms which demand treatment, then of course treatment should not be given until that disease gets in condition where the patient is suffering again, or where they need treatment

Q—Then, if a woman has symptoms in connection with some pelvic disturbance, and she is treated for the symptoms, and her pain is relieved, that woman considers that she is cured, and the doctor considers she is cured so far as those symptoms are concerned Isn't that a fact? A—That does not apply to her disease That applies merely to her symptoms

Q—That is what the doctor treats, isn't it? A—The doctor treats the disease, but he also treats the symptoms, because it is impossible to separate the two

Q—Didn't you testify on that occasion that the practice was to treat the symptoms? A—Why, very often we have to treat the symptoms, because the disease cannot be relieved For instance, in advanced cancer, where a woman is going to die of cancer, you can relieve the painful condition, but you may not be able to cure the disease

Q—I am talking about the menstrual disturbances or pain in connection with them or inflammation of the pelvic organs or the pelvic cavity which produces pain You do treat the symptoms in that class of cases, don't you? A—Why, the painful symptoms—

Q—I am talking about a case without a cancer A—The painful symptoms have to be treated, you have to relieve those and then you must cure the condition underlying it, if it is possible

The witness was then asked concerning his testimony regarding a number of remedies advised in the above-mentioned cases It was his recollection that there were tablets containing viburnum prunifolium with other drugs

The witness testified that he spends part of his time testifying in the court He probably testifies on an average of two or three times a week

Q—You were asked further "I will ask you if in your opinion, the treatment or the carrying on of a business through advertisements of this kind, and with this kind of treatment, is likely to be in any way dangerous to the party?" And your answer "I have thought that question over and I do not see how a thing which requires ten days use and then another application and the length of time—I do not see how any very acute illness could fall within the range of this treatment, because first, they must write for the remedy, and then get it back, and then take it The most acute cases would have been developed or terminated within the time The length of time necessary for the correspondence practically throws out that sort of ailment I do not see where the public life or public health, or the health of the patient would be greatly endangered, if at all, by this method There was a question brought up the other day that maybe a person would delay his treatment, and die of the disease by reason of the delay, notably cancer was quoted, that during the delay occasioned by this remedy a person might die of that disease or it might mature to such an extent that he had gone by the hopeful period I think the possibility of that happening with the type of cases which would answer this advertisement is almost infinitesimal I think that would happen so seldom that it is hardly to be considered" You made that statement, did you? A—Why, I think that is right

The witness then testified that in answering as to his opinion as to the use of the hypothetic medicine he based his opinion on his personal use of viburnum prunifolium and not on reading, but that he accepted everything stated in the hypothetic question concerning viburnum prunifolium as fact He knew of cnicus benedictus from instruction which he had received He formerly sold the drug in the form of a herb He sold it under the name of centaurea and chadron The people who used it were foreigners The witness testified that he does not know that all the pharmaceutical houses of the country make tinctures of carduus benedictus He has never experimented with the volatile oil

The witness was questioned specifically as to the content of carduus benedictus which is represented by cnicin and the relation of this portion to the entire extracted matter

Dr Adams mentioned the various conditions of the female uterus in which tannin might be used He defined a hepatic stimulant and stated in what way such a stimulant might be of service in the treatment of female diseases His remembrance of carduus benedictus is that it was used as a simple bitter, usually in the form of infusion

The witness does not know of any similarity between cnicin and quinin He defined a diuretic and a diaphoretic.

He stated that he used viburnum prunifolium for a number of years

Q—During that time you gave it to women with menstrual troubles? A—Yes, I used the drug quite a little

Q—And it contained 50 per cent. of alcohol? A—Not always I have used the fluidextract

Q—But that is only recently? A—And, Mr Hough, the fluid extract contains more than 50 per cent, if I remember right

Q—Fifty five per cent, is it not? A—It is 600 c c. of alcohol to 300 c c of water, I think is the menstruum

Q—You did not think, in giving it to women, that you were doing anything vicious, did you? A—Why, I tried the drug in that proportion, giving it in half teaspoonful doses, not in tablespoonful doses, and I did not decide that the effect of this drug was largely—in that form—was largely alcoholic, and not due to the drug value

Q—You say that there is, in your opinion, absolutely nothing in Wine of Cardui which would prevent a woman from taking it in constantly increasing doses? A—Nothing that I know of, no sir

Q—Did you ever drink it yourself? A—I have

Q—Did you increase the dose? A—No

Q—You say alcohol itself is not a food under any circumstances? A—My opinion is that it is not a food, because it poisons the individual before it can act as a food

Q—It does what? A—Because it poisons the individual before it acts as a food, and it is never a food except in a very limited sense indeed

Q—How does it poison the individual before it can act as a food? A—Well, it—that is, in small quantities it affects the will and lessens self control It has an effect upon the nervous system, especially in the young

Q—Does the percentage make any difference in your opinion? A—Naturally the larger the dose, the greater the amount of alcohol, the greater its effect

Q—Have you experimented any yourself in determining the physiological effect of alcohol in various proportions? A—In various proportions?

Q—Yes? A—No, I cannot say that I have

Q—Has your knowledge on that subject been gained by reading the literature? A—No, sir, it is based entirely upon what experience I have had with the use of alcohol and alcoholic substances

Q—How can you express any opinion on the subject if you have never experimented yourself? A—Well, the use of a remedy or the use of a drug in your practice, to my mind, is not the same as experimentation There you carry out a series of experiments to determine a point These are observations which I record from having used the drug

Q—Did the women that you gave the medicine containing alcohol to, acquire the alcoholic habit, any of them? A—I have never used alcohol or alcoholic drugs in sufficient quantity, or over a long period of time I have never given drugs indiscriminately to everyone, or other medicines I have always kept them under control

Q—Just answer my question? A—That is my answer

Q—Then you say they have acquired the alcohol habit? A—They have not

Q—Did any of the women you treated during the 30 years get well, or get relief from their symptoms? A—Yes, sure.

Q—What percentage got well? A—Of all kinds of cases?

Q—Of female troubles which had—which required no operation A—Oh, I think a large proportion of women recover under medical treatment

Q—I am asking you what proportion of yours got well? A—Well, of purely functional troubles, without displacements, tumors or anything of that sort, I believe that fully 50 per cent, perhaps more than that, would recover under proper treatment

Q—Then you mean you handed over the other 50 per cent to surgeons after trying to cure them or did you let them go? A—No I do not mean that a certain amount went to surgeons A certain amount of cases were relieved by mechanical supports, and a certain amount of cases would carry their defects through their lives, because it was not possible to operate, or it was—their mechanical supports would give them the needed relief

The witness was then cross-examined concerning the difference between relief and cure of various female diseases There was then read to the witness a statement from his testimony in Washington regarding what he meant when he used the words "bladder trouble" He replied that the remedies under discussion were to alleviate and were very seldom specific remedies The same thing was there stated regarding female troubles

Dr Adams stated that Mr Hough was reading symptoms from a card that were not in his statement Mr Hough replied that these were in the witness' statement and asked him if he wishes to change it He replied that it was immaterial

Further hearing of the case was adjourned until 2 o'clock the same day

May 2, 1916, Afternoon

Court met pursuant to recess Dr Nathaniel H Adams resumed the stand for further cross-examination by Mr Hough

CROSS-EXAMINATION BY MR. HOUGH (*continued*)

Dr Adams testified that a woman as a rule cannot diagnose her own case She can state when she has suppressed menstruation

Q—Now, what medicines do you usually give her for that? *A*—Why we must know If it is due to pregnancy, absolutely nothing If it is—

Q—Well suppose it is a young girl who is unmarried? *A*—Why my habit is to give her a good dose of quinin about two grains three times a day Give her a hot foot bath or mustard water, to give a hot drink of hot lemonade, and to put a hot water bottle at her back, the lower part of her back, and sometimes over her abdomen That is my custom and habit with young girls

Q—It is considered a safe thing to prescribe on account of the symptoms given by the patient, is it not? *A*—Such treatment with a young girl I should think would be safe

Q—Now, when a woman has painful menstruation, she tells a doctor that she has trouble at her menstrual period and she is able to diagnose that symptom and that condition isn't she? *A*—Not the condition. She is only able to diagnose the pain

Q—Well, I am not talking about the thing that caused it She knows that that is the symptom? *A*—Yes, she knows she is in pain, yes

Q—Now the first thing to do is to treat that symptom, isn t it? *A*—The symptom has to be treated And I will not say that that is the first thing to do, but it has to be treated, the pain has to be relieved until you find out what is the trouble what is causing the pain

Q—Well what medicines do you give in that class of cases when you reach the conclusion that it does not require a surgical operation? *A*—Well if it is due to a flexion of the womb to a bending of the womb why I give a sedative treatment, and I have the woman go to bed and use hot applications over the abdomen have her take hot drinks If there is a great deal of pain I give her sedative medicines

Q—Name some doctor *A*—Why, one that I am very apt to give is to give aspirin and sometimes a mixture of caffein and aspirin and acetanilid

Q—But you used to give viburnum compound? Haven't you? *A*—I have given viburnum compound yes

Q—And you used to give fluidextract of quassia? *A*—Of quassia?

Q—Yes *A*—I have never given quassia for that purpose alone

Q—And you have given fluidextract of pulsatilla haven t you? *A*—I have used pulsatilla in combination with other drugs yes sir

Q—And you have given fluidextract of gelsemium, haven t you? *A*—I have given gelsemium alone yes

Q—And you have given fluidextract of black haw?

The Court—Do you mean fluidextract?

The Witness—Fluidextract yes sir

The Court—Try and answer the questions doctor

The Witness—Yes sir I want to

Mr Hough *Q*—And also black haw? *A*—I have used all of those remedies

Q—For female diseases? *A*—I have tried them in female diseases yes sir

Q—Now you would give the same remedies for metrorrhagia and menorrhagia wouldn t you as far as the symptoms are concerned? *A*—Well I would if they had the same cause

Q—There is usually inflammation of the womb or the pelvic cavity in connection with all of those conditions is there not? *A*—No I don t think there is usually so I think it is often so There is often inflammation.

Q—Well in what per cent. of the cases? *A*—Why I think there is pelvic inflammation in dysmenorrhea in perhaps half the cases

Q—Now by the way pulsatilla is what you call a home remedy for those things, isn t it? *A*—No, sir pulsatilla is a powerful dangerous drug with a dose of two to ten drops

Q—Didn t you testify in Washington that it was a home remedy? *A*—Pulsatilla?

Q—Yes sir? *A*—No not alone no, sir it is not.

Q—Well we will see if we cannot find it for you Speaking of female diseases the Assistant Attorney General says Is there any other prescription Doctor you would use for that type, any internal remedies?

The Witness (Meaning yourself)—Yes sir They have a remedy similar to Hayden s Viburnum Compound Here is a tea This tea is used and is Remedy No 39 It contains cimicifuga gelsemium Jamaica dogwood fennel anise, caulophyllum viburnum prunifolium squaw vine aletris pulsatilla celery seed

The Assistant Attorney General *Q*—That is another home remedy?

The Witness *A*—No your Honor pulsatilla is a home remedy but this is a tea The herbs are cut up and set out in dry packages so much to a cup '

Mr Hough *Q*—You made that statement didn t you? *A*—But not in the sense that you asked me as though that was a simple remedy No it is a remedy that is used alone and I didn t mean that anybody puts pulsatilla in the hands of a family because it is a powerful dangerous drug

Q—What are the other home remedies which you referred to for female diseases? *A*—Well home remedies are the simple teas There is for instance the pennyroyal and things which can be used as hot drinks and which have no danger connected with them Such things are safe in the hands of families

Q—You did not consider that the alcohol in the medicines which you gave for those female troubles had any specific action as alcohol did you? *A*—Well, I would if I ever had given it in quantity to get the alcoholic effect, but when I used the alcohol in these remedies the alcohol carried its full drug content And the dose would be represented by half a teaspoonful or a teaspoonful

The Court—May we have a definition here of what is meant by a 'home remedy?

Mr Hough *Q*—What do you mean by a home remedy? *A*—Why I mean by a home remedy, a simple drug which can be put in the hands of a family for use in simple ailments without any danger of its doing harm if they make a mistake and take an overdose.

Q—What would be a home remedy for amenorrhea or suppressed menstruation? *A*—Quinin mustard foot baths hot drinks, or a little gin with an adult with a grown person, and hot lemonade, where the trouble is purely functional

Q—What would be a home remedy for dysmenorrhea?

The Court—Well let us get away from these indefinite terms What do you mean by a little gin?

The Witness—Yes I mean this, that gin is an alcoholic drug containing juniper and juniper in the quantity that is contained in gin and given in a hot drink, and given in one or two doses to a grown person and not continued, has a tendency to make an easy flow

The Court—Well how do you square that with your definition of a home remedy which as you have defined it includes some simple drug that cannot be harmful if you take an overdose? *A*—Well, gin of course could be harmful if it was taken in an overdose, there is no doubt about that. They can get drunk on it. And the reason of my mentioning gin is that it is a very commonly used preparation and I mentioned it because it has alcohol in it, and it has another drug and I think the knowledge of it is so general I think everybody knows it as well as a doctor, almost, that they don t take that in a poisonous dose, unless they want to get drunk.

Mr Hough *Q*—The effect of 48 drops of alcohol by itself is altogether different from the effect of 48 drops of alcohol in enough water to reduce the percentage to 20 per cent, isn't it? Or would you say the effect is just the same? *A*—Why, my opinion is that the effect is about the same

Q—Now do you think that you could take down in your mouth 48 drops of pure alcohol? *A*—Oh, do you mean the effect in my mouth?

Q—Well anywhere inside of you? *A*—Well, I misunderstood you Of course the local effect of 48 drops of alcohol is burning and you have to add enough water to it so as to permit you to swallow it

Q—Therefore you couldn't take 48 drops of pure alcohol in your mouth could you? *A*—I wouldn't want to

Q—Do you think anybody could? *A*—Yes, I think they could but I don t think it would be advisable

Q—Now when it is reduced to 50 per cent. it is easier to take that amount in your mouth, isn't it? *A*—Well, 50 per cent. is pretty strong That is the strength of whisky

Q—Yes and it is also the strength of the gin that you have just been talking about? *A*—The strength of gin yes sir

Q—Then when you reduce it to 40 per cent. its effect is less marked, isn t it? *A*—Well the local effect the local effect is less marked The general effect, in my opinion would be about the same.

Q—And the effect, when reduced to 20 per cent would be less still, wouldn t it? *A*—There would be very little local effect and you would have only the general effect to deal with

Q—Now how much alcohol can a person oxidize in the system freely? *A*—Freely?

Q—Yes? *A*—Well I think under the most favorable circumstances a 150 pound person in 24 hours can actually oxidize about an ounce and a half

Q—How many drops would that be? *A*—Four hundred eighty and 240—that would be 720 drops

Q—Of pure alcohol? *A*—Yes

Dr Adams was then asked concerning diagnosis as to the cause of a bearing-down feeling and pains during the menstrual period. He stated in what way he would arrive at a diagnosis

The witness stated that he makes a distinction between the classes of patients, as drugs and general treatment must be adapted to the circumstances of the patient He was asked to what extent he would say that a woman with female trouble could diagnose her own case

The witness was asked if he did not testify in Washington that it would be proper to treat on the diagnosis sent in by the patient. He replied that in certain cases when the patient had described the case completely and under certain conditions if one can arrive at a diagnosis and if he is sure of the case it would be proper to treat it. He was asked whether there would be danger in this way of overlooking consumption or cancer He replied that the likelihood of missing such conditions is greatly reduced by a physician s examination. He was asked concerning the use of medicines to make the breasts full. He stated that drugs are given when there is insufficient lactation after childbirth and that certain drugs may be taken for cosmetic purposes

Q—What do you mean by "cosmetic purposes?" *A*—Why, I mean that by rubbing in ointments, and perhaps there are one or two drugs, they have a tendency to make a full breast which women sometimes desire

Q—Well, you also take medicines by the mouth for those things, don't you? *A*—There are one or two drugs. There is a drug called Goat's rue or galega which has a reputation for doing that sort of thing

Q—And Heminal? *A*—What?

Q—Heminal? *A*—Heminal, that is an iron preparation

Q—It is a hemoglobin preparation, isn't it? *A*—Yes

Q—And it is used to develop the bust? *A*—Why, it is used to improve the quality of the blood If a woman was anemic, why, I presume it would have that effect

Q—Didn't you testify it was used to develop the busts *A*—Why, not to my knowledge It is a blood remedy If I testified to any thing like that it was in some other connection, of which you have not given me the distinction You have picked that out and not given me what goes before and of what follows

Mr Hough (Reading)—"I show you also two other prescriptions marked 2 B and 1 B? *A*—2 B is heminal, three grain tablets

'What is that prescribed for? '*A*—Heminal is practically a Parke Davis preparation Made for the blood It is a *hemoglobin preparation* and contains iron and is prescribed to enrich the blood One B contains extract of galega, one and one half grains, calcium lacto phosphate, two grains, and oil of fennel, one tenth grain This remedy is used to develop the bust and to cause an increase in the quantity of milk in a nursing woman"

The Witness *A*—That applies to that latter description Yes, sir, I think that is all right That is what I stated, and is what I still believe.

Mr Hough *Q*—Well, that is proper to give to a woman who is nursing, isn't it, to develop the bust? *A*—Galega—why, it has a reputed action in that way It is reputed to be able to increase the size of the bust

Mr Hough—Well, didn't you say—I will read further (Reading)

The Assistant Attorney General—Is it proper to give that to a woman who is not nursing?"

And the witness (meaning yourself) "*A*—Yes, your Honor, it is".

Mr Hough—You made that statement, didn't you? *A*—Well, I have just stated it is reputed to have a good effect

The witness was then asked concerning his testimony at Washington regarding the use of certain drugs for restoring sexual function on the basis of a filled out blank sent in by the patient defining his condition

Dr Adams defined his understanding of uterine tonics and uterine sedatives He had used liquor sedans in the past because it contains hydrastis, which he considers a valuable drug He knew the amount of alcohol in this preparation He gave it three times a day, but did not consider it wise to place it in the hands of a patient Ordinarily he used no treatment at the time of the menopause As a rule he used sedatives to allay nervous irritability It was brought out at Washington that the witness had answered that he considered the use of the mixture under the name of Mother's Cordial highly beneficial to a woman in the change of life period

The witness then discussed the composition of this preparation further with reference to its alcohol content and stated that to his knowledge it need not necessarily have alcohol

Q—Well, at any rate that medicine, in your opinion, would be highly beneficial to women in change of life period? *A*—Why, I think there are some valuable drugs in that prescription, yes, sir

The Court—You mean generally, in the absence of any symptoms whatever? *A*—Oh, no, no If they need it If there is a need of medicine If she did not need medicine, if there are no symptoms, it should not be given

The Court—I mean symptoms other than the normal symptoms of change of life? *A*—If she has just the normal change of life she should not have any medicine It is not indicated

Mr Hough *Q*—Well, the change of life in a perfectly normal woman, of course, is not—I mean it is purely physiological? *A*—Yes, sir

Q—And the same is true of menstruation, and the same is true of puberty, and the same is true of pregnancy, isn't it? *A*—True

The witness stated that it was his opinion that 75 per cent of the women go through the menopause without trouble About 75 per cent of all women are apt to have simple nervous manifestations which do not need any particular treatment It was brought out that at Washington the witness stated I think in fully 75 per cent of the cases this medicine 'Mother's Cordial' would be beneficial"

Q—Well, you made that statement, didn't you, that 75 per cent of the cases, in 75 per cent of the cases it would be beneficial? *A*—Well, that was asked in regard to that particular tea, and I don't see why that should not be used

Q—It is a medicine, isn't it? *A*—Yes

Q—And you would not give medicines when they were not needed at all, would you? *A*—Well, I don't believe in giving medicines where they are not needed But that is about the possible use of such a preparation

Mr Hough—And the Assistant Attorney General then said (Reading)

"In old women after change of life?" And you replied

'If they had any female trouble, yes, your Honor"

'*The Assistant Attorney General*—They may have female trouble which is not amenable to treatment of that kind?"

'*The Witness*—This happens to be treatment which practically is indicated in almost every case."

The Witness *A*—Well, it is all right It is harmless

Mr Hough (Continuing *reading*)—"Just think of that wide range of possibilities in that jurisdiction It is soothing and there is an eliminative treatment and a gentle cathartic There is a whole drug store in that"

The Witness—I think that is right

Mr Hough *Q*—And, Dr Kebler then said to you (Reading) "What good would it do in ovarian troubles?"

"*The Witness*—I think it would allay the pains Jamaica dogwood and those remedies—just turn to the uses of them That would be *an ideal symptom for* Jamaica dogwood It is soothing and quieting"

Mr Hough—Is that correct? *A*—I think that is right

Mr Hough—(Continuing reading)

"*Dr Kebler*—How would they help in tumor or in prolapse of the uterus or lots of other things?"

The Witness—No, just limit me to one at a time Take cancer Of course, by their method you would soon eliminate cancer, because that is a disease which would put that woman beyond reach of this condition, but here is the eliminant medicine and the medicine to gently relieve the bowels and the medicine which would soothe and quiet the part It might be argued that delay in this matter would put her beyond the pale of health, that delaying treatment by such a method as this would remove her chances I will say this about cancer, that any treatment of this sort over the time it extends, if it was unrecognized, it would certainly delay the case some, but I do not think practically we ever get hold of cancer of the womb until they are pretty far advanced *I think that is where we are all weak and* a large proportion of cancer of the womb cases that have come to us have gotten beyond the operation stage by the time we reach them But this treatment will never replace surgery in cancer of the womb"

Mr Hough *Q*—You made that statement, didn't you? *A*—I think that is true, that cancers come to us so far advanced—I mean speaking as a general physician—that cancers come to the office in a majority of cases so far advanced that they have to be simply relieved That the hope of cure is by That is the one thing we all are hoping for, to get at these cases early, and to recognize them so we can do some good

Q—Now, then, did you say also that "it would be useful, this medicine, if it was inoperable cancer It would be useful in any kind of cancer, but if it would in any occasion delay it would not be useful in that instance"?

The Witness *A*—Why, that is true If it would delay the recognition of cancer in any way it would be absolutely wrong

Q—But you also stated that you thought that would be true in a very small proportion of cases? *A*—Well, because I—I stated that if they had cancer, I thought they would go to the doctor, and the doctor would recognize it

Q—You stated that would be a very small proportion of cases, didn't you? *A*—Yes, because they would go to a doctor, it would be so serious they would go to a doctor and have it recognized

Q—You use medicine for apparently opposite conditions, don't you, the same medicine? *A*—Well, there are a few drugs that—

Q—Just answer that question? *A*—Yes, there are a few drugs that will act in apparently opposite conditions

The witness was then asked concerning empiricism in medicine and the distinction between "patent" and proprietary medicines He stated that for some time he has been connected with the manufacture of proprietary medicines which were for sale to anybody that would buy them The witness stated that it is a question of dispute whether all proprietary medicines are ethical or unethical

REDIRECT EXAMINATION BY MR T J SCOFIELD

On redirect examination Dr Adams stated that he would not give a medicine containing alcohol to a pregnant woman with Bright's disease because it would be dangerous He stated that digitalis is a medicine which may act in opposite conditions, meaning at the same time a heart sedative and a heart tonic A uterine sedative which will keep the womb quiet may give the blood vessels sufficient time to nourish the womb and remove the waste, and in that sense it may be considered a tonic

RECROSS-EXAMINATION BY MR HOUGH

The witness testified that even though all the alcohol given to a pregnant woman with Bright's disease were oxidized it still would have a bad effect because of its action on the nervous system and because it adds a poisonous drug to the system There is more work thrown on the kidneys because of the ash produced by the cells in oxidizing alcohol

TESTIMONY OF DR G M GODDARD

Dr G M Goddard was called as witness for the defendants

DIRECT EXAMINATION BY MR LOESCH

Dr Goddard testified that he resides in Waxahachie, Texas, where he has lived for nearly four years He has practiced medicine since 1890, first in Van Zandt County, Texas, later in Ovilla, then in Oak Cliff and then in Boyce Later he practiced in Taylor County in West Texas and then moved back to where he is now living He was graduated from the Kentucky School of Medicine, Louisville, Ky, in 1895 He has had several cases in which Wine of Cardui figured The first was Mrs W, whom he treated in 1892 She was suffering with uterine hemorrhage and painful menstruation as well as other pains accompanying these conditions He ascertained from her that she had been in ill health with dysmenorrhea and hemorrhage for three or four years, and that she had been taking Wine of Cardui almost incessantly Sometimes she would consume a bottle in a day Mrs W was about 35 years old

The witness then mentioned a Mrs D, whose condition was similar to that of Mrs W, only not so exaggerated He stated that she had been taking Wine of Cardui a little more than a year without any improvement He gave her practically the same treatment that was given to Mrs W, an antimalarial treatment, packing of the uterus with gauze She became well He diagnosed her condition as malaria with hemorrhage He had seen Mrs D pour one half or two thirds of a teacup of Wine of Cardui and drink it This case was also in 1892 When he was living at Walton Mrs D was about 30 years old

The next case was a widow, Mrs B, who had a similar condition He gave her iron, quinin and arsenic in pill form and she recovered She had been taking Wine of Cardui for about a year, and claimed that it did not do her any good

The next case was a step-daughter of a man named Mr L Dr Goddard attended her in confinement. At that time she had puerperal convulsions She said she had been taking Wine of Cardui since the third of fourth month of her pregnancy because of headaches and swelling of the feet.

The witness then mentioned the case of Mrs Du She had prolapsus and severe hemorrhage at each menstrual flow and at each time she would have to go to bed He advised operation, to which the patient would not consent. He used tampons, ichthyol and glycerin, but did not do much good The patient told him she had been taking Wine of Cardui for three or four years off and on She also stated that she had not obtained any relief from Wine of Cardui

Q—What was your next case, Doctor? *A*—The next case I had was a Mrs. J who had a case of gonorrhea She had been taking—she had had the gonorrhea about three months before they consulted me and had been taking Wine of Cardui during the time Now she didn t know that she had gonorrhea and doesn t know it to this day She was inoculated by her husband infected by her husband I was treating her husband at the time and cautioned him about his wife She contracted the gonorrhea from him and had had it for about three months before they came to me, and she stated that she had been taking the Wine of Cardui during this time, thinking that it was the change of life working on her and that was her condition. She had a real bad case of gonorrhea when I saw her

Q—Did you treat her so as to produce a cure? *A*—Yes sir Well I got her in much better condition Now we thought she was cured at least

Q—How old a woman was she? *A*—She was about 40—she was between forty and forty five years old Really I believe 42 or 43 years old

The next case was Mrs J B—a young woman with a gonorrheal infection She suffered with pain, burning sensation and discharge. In this case also Dr Goddard had been treating the husband. The patient had been taking Wine of Cardui for two or three months, but it did not do any good If taken over a long time he believed it seems to aggravate the condition

Dr Goddard stated that the patients told him that the longer they take it the more they take of it and the worse the conditions become

The next case was that of Miss Du—daughter of Mrs Du previously mentioned She suffered from delayed menstruation She had been taking Wine of Cardui more than a year without benefit She was about 19 years old She had malaria and was given antimalarial treatment and recovered

The next was the case of a Mexican girl, the daughter of a man named Mr P She was pale and anemic, had a cough and had never menstruated He diagnosed the case as tuberculosis and the patient died of this condition six months later She had been using Wine of Cardui for two years They told Dr Goddard it had done no good

Q—What was the next case, Doctor? *A*—Another Mexican girl She was seventeen years old That was just about the same case as this one The Mexicans were all in a bunch, they were a bunch of cotton pickers She came to me about two or three months later than the first one did, and with just about the same history, only she had been taking Wine of Cardui a year, she claimed. That is the history she gave me

Q—What was her condition? *A*—She had tuberculosis, and died in six or eight months or a year, something like that after I saw her

Another case was Miss M—a young lady about 18 years old She gave the history that she would menstruate about three or four times a year She had been taking Wine of Cardui about four years This patient died of tuberculosis and had no beneficial effect from the Wine of Cardui

The next case was Mrs W C S, who suffered with frequent miscarriages She had taken Wine of Cardui but it had not done her any good He advised her to quit taking Wine of Cardui About a year and a half later he waited on her in a full term confinement

A Mexican woman came to Dr Goddard with a baby 3 weeks old She had taken Wine of Cardui during pregnancy with a view to making her labor easy After the baby was born she had an abscess of the breast She was taking Wine of Cardui and had a high fever The abscess was opened, the pus withdrawn and the patient had no further trouble

Q—What is the next case you have, Doctor? *A*—Well I had a case of pellagra a negro A K.s wife that had pellagra for quite a long time a year or better, and she had an awful bad prolapse before she died The womb was protruding clear out. And she had been taking the Wine of Cardui during the time, this period of about a year before I saw her, with a view that she had some female trouble that was what she thought But she had pellagra and died of pellagra

Q—To what extent had she been using Wine of Cardui? *A*—She had been using it steady for—for about a year—the history they gave me

Q—Did she tell you what doses she took? *A*—She had been taking it in pretty big doses she used to take a third of a teacup full

Q—You saw her take it? *A*—I saw her drink it out of a bottle.

The wife of a negro named W H was suffering with an enlarged uterus and would have severe cramps at the time of menstruation Dr Goddard testified that he advised an operation, but the patient would not have it He saw her pour Wine of Cardui into a cup, add water and drink the mixture. She stated that she had been taking it for two or three years, but it did not do her any good.

The next case was Mrs W She gave a history of scant menstruation and wanted tonics She was married and was anxious to become pregnant She had been taking Wine of Cardui for more than a year The patient refused to be examined Dr Goddard was again called about three months later and he made an examination and found the mouth of the cervix tight He dilated and curetted the uterus About four or five months later the patient became pregnant and was later delivered of a full term child

Dr Goddard was then asked to describe instances in which Wine of Cardui was used as a beverage

Q—Well tell the instances where you know of it being used as a beverage *A*—Well I had a man by the name of Nelson that came to me up in Oklahoma Territory—it was a territory then He was a man who was addicted to the whisky habit and he could not get whisky at all times in his section of the country, and he used to use—he got to drinking Wine of Cardui, so he stated And when he came to me he was—came to me for treatment for the alcoholic habit—alcoholism

Q—How long had he been drinking Cardui? *A*—I believe he told me that he had been drinking it for better than a year—not all the time now, but when he could not get whisky

Q—And he used it—didn t he state to you that he used it for three or four years?

Mr Walker —Well—what's the use?

The Witness —I don't call that to mind He had been drinking for longer than that, but now—I don't—but he had been using the Wine of Cardui for a year—for about two years

He also recalled a case of a man named B R, who drank lots of whisky, when he could not get whisky he would drink anything he could get hold of

THE COURT —Now, is this what you know of your own knowledge, or as his general reputation?

The Witness —I know that he has drunk different "patent medicines," your Honor, and he has come to my house just as drunk as you ever saw a man, most, drinking Wine of Cardui He would have it in his buggy I have seen the bottles in his buggy I have taken him out of his buggy—taken the man out of his buggy and put him on a pallet on my porch, and kept him there half a day at a time I have done that, I will say, as many as half a dozen times, till he would get sobered up I have seen him drink a bottle of Wine of Cardui at one time, just take the cork out of the bottle and clean it up at one drink

Dr Goddard testified that he has also seen a man named W who would drink large quantities of Wine of Cardui He has seen him empty a bottle in three or four drinks

Dr Goddard then described the case of B, who was addicted to morphin and would also drink whisky when he could get it He would drink Wine of Cardui

He also described the case of S, who lived in a dry territory He would drink whisky when he could get it, but when he could not get it he would drink Wine of Cardui

The latter cases were treated in a sanitarium for drug addicts which Dr Goddard conducted

Q —Have you an instance of any woman using it as a beverage? *A* —Yes, sir Some of the women—patients that I would have

Q —Mention them? *A* —Why, I had one, an old lady—I don't remember her name Her daughter lived in Dallas and brought her over to the sanitarium, and I could not give you her—I don't know her daughter's name They lived—that is, the daughter lived in Dallas And in giving her history, she said that she had been back some years before that—that woman was then about 55 years old—that she was using Wine of Cardui She was taking morphin, and at the same time was using—she would drink Wine of Cardui She said that when she—back before her menstrual period—I mean, before her menopause—that she suffered so that she got to taking Wine of Cardui to tide her through her change of life, as she gave it to me, and it got to where she would not—she could not—she got no relief from it, and she would keep increasing the doses—and she got to using—mixing morphin with it She would take morphin in small quantities with her Wine of Cardui to get the ease—to get relief, and from that she went on and got in the habit of using morphin, and when she would run shy of morphin—that is, could not get enough of it, or she did not have as much as she wanted or needed, she could take the—increase the dose of Cardui, and could get along on less morphin And her daughter—she or the old lady, stated that she would take the Cardui, that it would make her dizzy when she would take big doses of it, it would make her dizzy, make her head swim She did not say she was getting drunk on it, or anything like that, but that is the statement that she and her daughter both made to me in my office

Q —Did you ever see her drink it? *A* —Yes, sir

Q —That is, drink Cardui? *A* —Yes, sir I saw her drink Wine of Cardui

Q —How much have you seen her drink at a single time? *A* —I have seen her drink a third of a bottle

Q —How long was she under your care, Doctor? *A* —She was there about a month with me. I usually kept them about a month

Dr Goddard also described a patient—wife of a traveling man—who was a morphin patient and had been using Wine of Cardui for painful menstrual disorders, and later began to take morphin This woman would drink as much as one-third of a bottle at a dose

Another woman named Mrs S would pour Wine of Cardui into a teacup, add water, and drink the mixture When drinking this mixture she could get along with less morphin

Another patient, a woman from Denison, Texas, stated that she commenced using Wine of Cardui to help her through painful menstruation and finally drifted to mixing morphin with it She would drink it out of the bottle, taking three or four tablespoonfuls, perhaps, at a dose

Another case was a woman from East Texas with the same history This patient would turn up a bottle and take two or three swallows from it

The witness stated that he has been in Chicago several weeks, perhaps three weeks or more, and that he had remained in Chicago since the adjournment at Mr Loesch's request

The court was adjourned until 10 30 o'clock Wednesday, May 3, 1916

May 3, 1916, Morning

The Court met pursuant to adjournment Dr G M Goddard resumed the stand

CROSS-EXAMINATION BY MR WALKER

Dr Goddard testified that he received a letter from Dr Taylor, secretary of the Texas State Medical Association He met Dr Heizer at a meeting of the Southern Medical Association in Dallas He testified that Dr Heizer asked him if he knew of any people who used or drank Wine of Cardui and requested him to look up the matter

Dr Goddard was cross-examined concerning the names of the persons mentioned in the direct examination The witness arrived in Chicago about March 21 and has been here about five weeks He is receiving his expenses and a per diem He was cross-examined concerning his various locations in practice and his connection with the sanatorium at Oak Cliff He was then cross-examined concerning the names of various people whom he treated at the sanatorium He testified that he had made no special endeavor, after he was asked by Dr Heizer to do so, to look up the persons mentioned in the direct testimony

Q —Will you tell the jury how it is that you remember their history, when you cannot remember their names? These people from the various points of the compass in Texas? *A* —These people would come in and, getting the history of them—why I just call to mind from memory we would make a record of the case The old lady in using the morphin, she was the first patient that I had gotten hold of that come to my institution—

Mr Loesch —A little louder

Mr Walker —Speak out loud, we don't hear you

A —The old lady that came was the first woman that come to my sanitarium that gave a history of having used—having been using Wine of Cardui and went to taking morphin That first attracted my attention to it in making out the history of these I don't just—it is just the particular condition of the case is all that I can call to mind that makes me remember it I remember these distinctly, the morphin patients, and having the stuff in their grip calls it to my mind Now, as to just any special thing that just calls to mind—without quite a number of patients that we had—we had quite a number but these were the only ones that used the Wine of Cardui in connection with morphin

Q —The list that you made up of those names, when did you make it up, in reference to your coming to Chicago? You say you made it up before you came? *A* —Well, I don't know that I could—that there was any certain day I had it I made out the list of names some of these—which do you mean, do you mean all of the names, or do you mean—

Q —Was there any of them that you recollect that you made out after you came to Chicago, and heard some of the testimony in this case? *A* —No, sir

Q —Then I take it that all the names that you have mentioned to this jury were listed by you before you came to Chicago, and after Sizer saw you, is that right? *A* —Yes, sir

Mr Loesch —Heizer

Mr Walker —What did I call him?

Mr Loesch —You just leave off the "Doctor" and say, Sizer, instead of Heizer

Mr Walker —Yes, Sizer examined the evidence on the drunks and the doctor got them

Mr Loesch —Sizer and Heizer, lawyer and doctor

The Witness —Sizer never examined them

Mr Loesch —Well, they are here

Mr Walker —Yes, and they are some specimens to be proud of

Dr Goddard was then again repeatedly cross-examined in an endeavor to recall to his memory the names of the patients treated in the sanitarium The witness then testified on cross-examination as to the various places in which he practiced from 1890 up to the present time

Q —Can you give me the name of any one person that you ever saw drink Wine of Cardui, or any woman that gave you in her history that drank Wine of Cardui, that is now living anywhere that you can tell us the location and name of? *A* —I can tell you where they were when I saw them last. I do not know where they are now

Q —But I am asking you about now? *A* —No, sir

Q —Is there any one whose name you can give us that is living who used Wine of Cardui as a beverage, or any woman who gave it as a part of her history, that you can tell us, that you know was living and where the person lived when you first met Heizer? *A* —No, sir, I don't know where they lived

Q —When was the last person, the date now, that you ever saw drink Wine of Cardui, as a beverage, or any you have named? The last date? *A* —That was when I was running the sanitarium *1900 and 1901*

Q —That is the last date of any man you ever saw drink it as a beverage? *A* —Yes, sir

Q —Give me the name Was that man or woman? *A* —Both

Q—At the sanitarium One of them was an alcoholic, and the other ones were morphin fiends when they came to see you? *A*—Yes, sir there was two of them, two of them

Q—Now— *A*—Wait a moment, what was that you asked me?

Q—I say one of them was an alcoholic, S from Oklahoma? *A*—B from Oklahoma B was a morphin fiend, and the rest of the men were alcoholics You have just got it reversed

Q—When was it that you saw N? *A*—N was in 1902

Q—Where was that? *A*—That was in my house He called on me to treat him for alcoholism and he stayed in my home

Q—At which place were you then living? *A*—I was living in Oak Cliff then and I was running the sanitarium

Q—Did he live in your house, while he was there? *A*—He had a room in my house yes sir, boarded with me.

Q—S— *A*—N his name was N

Q—Did any member of your family see N drink Wine of Cardui? *A*—I don't know about that I don't suppose they did

Q—Is there any other member of your family here? *A*—No, sir

Q—Any of these cases that you have named can you give me the name of any other individual on earth that saw them drink Wine of Cardui as a beverage, any one of them? *A*—All the people now that you are talking about?

Q—Any one of them I am speaking now of the people that drank it as a beverage Can you give me the name of any one that you have named of any person? *A*—Well, the help that I had in the sanitarium might have seen them I do not know whether they did or not I could not say for that

Q—As far as you know, nobody else but yourself ever saw these people drink Wine of Cardui? *A*—No I do not know that they did, not around me, not only the ones that was in the sanitarium

The witness was then again cross-examined concerning the names of the patients whom he treated who took Wine of Cardui

TESTIMONY OF DR C HUGH M'KENNA

Dr McKenna was called as a witness for the defendants

DIRECT EXAMINATION BY MR T J SCOFIELD

Dr McKenna testified that he has resided in Chicago for sixteen years He devotes more attention to surgery than to general medicine He graduated from the Rush Medical College in 1903 He then spent a year as intern and assistant to the late Dr Nicholas Senn later for about four years was assistant to the late Ferdinand Henrotin He was abroad in 1909 and again in 1910 In 1909 until about 1913, he was associated with Dr John B Murphy in the capacity of associate chief of St Joseph's Hospital In 1913, Dr McKenna was appointed surgeon in chief, and president of the staff of St Joseph's Hospital

In the treatment of diseases he uses both mechanical and medical means if indicated Dr McKenna testified that he has had no experience with cnicus or carduus benedictus

Q—Now doctor will you tell the jury what experience you have had in the use of viburnum prunifolium and what conclusions you have reached as a result of your experience with it, as to its therapeutic value? *A*—Early in my practice I used viburnum prunifolium and I used it particularly in the extract in the dry form I should say that I used it over a period of probably five years and owing to the fact that I had no results from it at all I discontinued its use

Q—Now when you say you used it in the dry form what do you mean by that, doctor? *A*—Well I mean that if I remember correctly I had Burroughs & Wellcome an English firm put up viburnum prunifolium in the form of tablets used in connection with small doses of the tinctura opii camphorata also in a powdered form making it more easy to be used by the patient

After using it for a time I figured that the only effect I got from it was the paregoric and then trying the drug alone I got no effects and discontinued its use

Q—Then in your use of viburnum prunifolium you did not use it in the form of a fluid at all? *A*—Well I might say that I probably have written ten or a dozen prescriptions of the fluidextract of viburnum prunifolium

Q—But with the exception of those prescriptions your experience in the use of the drug was in the dry form? *A*—Yes sir

There was then asked the witness a hypothetical question similar to that asked of previous witnesses and he stated that he had an opinion as to the physiologic action and therapeutic value of the hypothetical medicine

Dr McKenna testified that such a medicine would not be proper scientific treatment for the various uterine displacements

Q—Why not doctor? *A*—It would have absolutely no effect upon the organ They are out of place. That is to say retroversion retroflexion anteversion and anteflexion, and if they are caused by certain inflammatory conditions pressing down upon them such as pyosalpinx or any other pathological conditions within the pelvis it would be absurd to feel that any medicine would have any effect upon these conditions

There was then described to Dr McKenna an experiment similar to that described by Dr J Clarence Webster and he stated that such an experiment would confirm the opinion which he had expressed Such an experiment would cause him to believe that the hypothetical medicine was not a uterine tonic Dr McKenna testified that puberty, pregnancy, the lying-in period and the menopause are normal physiologic conditions and that in a large majority of cases they require no medication whatever The menopause is a very dangerous time to give any medicines that might mask the symptoms of some pathologic condition which might occur

Q—I say but going back to the age of puberty, you say that it is an impressionable period in the history of a girl and that it is the one period particularly when no alcohol should be administered Now why is that Doctor? *A*—Well, it is at a time when the young girl is going through a change that psychologically, or so far as the question of her mental makeup is concerned she should not receive anything that is of a stimulating character, because of this change through which she is passing at that period

Q—What would be the effect if anything of the alcohol contained in such a medicine at such a time, used as frequently as is advised here three to four times a day, three times a day, upon the question of the excitability of the girl's passions? *A*—I did not catch the last part

Q—Upon the question of the excitability of her sexual passions? *A*—I said that at that time young girls are of a very impressionable age They are very apt to acquire a habit and particularly at a time when a new period has come into their lives from the standpoint of the change in the sexual organs and it is very likely of course to stimulate them markedly in that respect.

Dr McKenna testified that menorrhagia and metrorrhagia are symptoms of disease In explaining he described

Q—Now when you say they are symptoms of disease what do you mean by that doctor? *A*—I mean that there is a varying number of abnormal conditions occurring in the female organs which may cause a woman to flow that may cause an increased flow at the normal period the monthly period, or it may cause a flow between the periods The conditions that bring about this flow are varied They come on sometimes very insidiously without a woman noting any condition herself at all I might refer to a patient that I have had in my experience within the last few weeks A woman 42 years of age.

Q—Have you got anything here to illustrate that case? *A*—Yes I have

Q—Will you please produce it bring it up here

The Witness—May I stand up?

The Court—Certainly?

Mr T J Scofield—Doctor stand on this side (the witness produced three glass jars each containing certain specimens hereinafter referred to and described, and the said jars and their contents were within view of the jury)

The Witness—This woman that I refer to is 42 years of age approximately She came into my office at 104 South Michigan Avenue about two and a half weeks ago Practically the only history that she gave was the history of flooding as she expressed it. She had no pain no pain referable to her pelvic organs

She said that she had been flowing for a matter of over two weeks and was flowing so heavily on that day that she did not wish me to examine her as she expressed it and I told her that under those circumstances that it would be well for her to go somewhere where she could be put to rest immediately

I recommended that she go to the hospital which she consented to do I examined her at the hospital However she did not go to the hospital directly that night but rather came there the next morning and under the proper aseptic conditions I examined that patient and found a small submucous fibroid which is a small growth presenting in the canal of the womb presenting somewhat in that manner (the witness illustrates by encircling the end of his little finger with the first finger of the left hand so that the tip of the little finger protrudes about one quarter of an inch) through the opening of the canal leading down from the womb

Upon further bimanual examination I found that she was suffering with a good sized fibroid, as represented in this jar (Referring to one of the jars hereinbefore produced) Now the only symptom that that patient complained of was the question of flooding She had no pain no other symptom at all and I felt that it was a very important case particularly from the standpoint of showing that there is absolutely no way in which a woman can tell whether that is an operative case or not

I present here also a second case that was operated on pathological number 5070 was operated on April 15 of this year the fibroid of the uterus and the small submucous fibroid of the cervical canal I present also a second specimen—

Q—Doctor is this the fibroid here taken away from the woman? (Referring to contents of one of the jars) *A*—That is the fibroid. She was operated on October 15 (The witness apparently intended to say April 15)

Q—What is her condition now Doctor? *A*—She was discharged today feeling perfectly all right

Q—Go ahead? *A*—I present also a second specimen This represents what is known as a double dermoid cyst of the two ovaries and was operated by me on March 14 of this year

Mr Walker—That is the middle one? (Referring to the position of the jars.)

The Witness —That is these two This is the right ovarian tumor, and this is the left ovarian tumor (Indicating contents of jar No 2)

Mr T J Scofield Q —The same patient? A —The same patient Now, this woman I saw on the morning of March 14 and the only symptom she had, referable to her pelvis, was slight metrorrhagia, or flowing between the periods She had some cramps in the abdomen, but so far as the pelvis was concerned, her symptoms were a slight metrorrhagia

Now that patient was examined, and it was decided that it was one of two conditions either a strangulated or twisted pedicle of a hemorrhagic ovarian cyst, or an ectopic pregnancy

She was immediately sent to the operating room and operated and we found blood flowing freely into the abdomen from a twisted ovarian pedicle, the upper half of the tumor being made up of what is known as dermoid and containing hair, and in this instance some bone and various other tissues, which comes about in conditions (if we bring it down to a question of the development of the fetus) where certain layers come together while the fetus is still in utero or within the womb and there is malformation at that time

Now this, on the right side, was a mixed dermoid and hemorrhagic cyst and on the left side, was a large tumor taking up the entire ovary The entire ovary—in fact, there was not any true ovarian tissue at all As I stated before, this case was ruptured and was bleeding into the abdomen, and if it had not been recognized within a period of a day or such a matter, she could very easily have bled to death

Now the patient was immediately operated and made a good recovery and left the hospital I think in a period, I think, of about three weeks or three and a half I do not know the exact date The number of the second set of specimens is 5020 I gave the first one, 5070, I guess, did I not?

The Reporter —Yes, I think so

The Witness —The second one is pathological number 5020 The history and names of these patients are here for anybody who wants them

Mr T J Scofield Q —Now, doctor, let me ask you whether or not these cases that you have just been describing are illustrative of many other cases which you have had in your practice? A —Many, and I—

Q —Now, I suppose—go ahead A —and I particularly wish to point out to this jury the fact that it is impossible not only for any patient suffering with the condition as described in the second set of specimens there, namely, the hemorrhagic cyst of the ovary, to determine what that condition is, but it is practically impossible for a medical man after he has given the patient the most searching examination, to say whether that is an ectopic pregnancy, by that I mean a conception without the womb, or a hemorrhagic cyst, so that the question of stating that certain conditions are not treated because they are operative conditions—here is a condition in point, that nobody but the doctor and under the most searching examination can tell what the condition is

Q —Now, doctor, as I understand it, you, as a surgeon, and as a doctor, could not diagnose the condition from the symptoms which the patient disclosed to you? A —In no way

Q —And as to at least one of these cases, you, as a physician and a surgeon, could not with certainty diagnose the exact condition there after examination, until after you had opened the abdomen? A —In the case of the second case, that is the hemorrhagic cyst of the ovary, no

Q —You were able to determine— A —I expected that it was an operative case, and that it should be operated immediatly

Q —Now, how could you tell that it was an operative case, from what the patient told you? A —No, from my examination, which consisted in the bimanual examination, placing one hand in the uterus of the patient, or in the vagina of the patient, and the other hand over the abdomen, and examining in what we call a bimanual way, and in addition to that, making the necessary laboratory examinations, such as the blood count, that go with that type of examination

Q —Then, if I understand you aright, doctor, in the treatment of those two cases, you did by your examination discover abnormal conditions that the symptoms as manifested, or told you by the patient, did not disclose? A —Exactly

Q —So far as the complaints—

Mr Hough —I do not see that this is material

The Court —Which?

Mr Hough —His question, and the answer

The Court —I do not think it is myself, but nothing was said about it, until it got by us

Mr Hough —I did not catch it

Dr McKenna testified that the hypothetical medicine would not be a proper scientific treatment in cases of menorrhagia and metrorrhagia

There was then read to him a statement from the Ladies Birthday Almanac concerning flooding He stated that it was absolutely incorrect and misleading to state that

> "Flooding is always a sign of danger The best treatment is complete rest in bed, and Wine of Cardui three times a day"

Dr McKenna then described other conditions such as sarcoma, or cancer, which might bring on similar symptoms as those of the cases previously mentioned These symptoms might also be produced by inflammation of the fallopian tubes He stated that a medicine similar to Wine of Cardui would do no good in cases of menorrhagia or flooding

There was then read to Dr McKenna a statement from the Ladies' Birthday Almanac and he was shown a picture from the pamphlet illustrating a woman with her hand at the small of her back He was asked to state to the jury the conditions which might arise within a woman which might be the underlying cause for such a pain in the back as the picture and the paragraph described He stated that there were many conditions He mentioned particularly tuberculosis of the spine and metastatic infection of the intervertebral spaces He treated cases of this kind by removal of the focus of infection An early recognition of the condition is necessary He mentioned also the mechanical treatment by immobilization, also the use of vaccines He mentioned the use of the steel corset in the treatment of metastatic infection of joints He also described in general the treatment of tuberculosis of the spine

Mr Hough —Just one moment Do I understand the witness to say that when a man or a woman has a pain in the back, that this is his condition?

The Witness —No, sir, I did not say any such thing

Mr Hough —Then this is immaterial

The Court —I thought it was immaterial This is one of the things that may cause pain in this particular point in the back, shown in the picture

Mr Hough —Anything can cause a pain in the back I thought he said if any one had a pain in the back, they had to have this thing

Mr T J Scofield —He did not say that, and from what you inferred it, I do not know But he said that a pain in the back might be due to, or result from such a condition Then I asked him what different conditions might produce such a thing and now he is answering

Q —Now, Doctor, let me ask you whether or not such a condition as you have been describing would produce the sort of symptoms of pain that has been described and read to you, from this Ladies' Birthday Almanac? A —It would

Q —Would that case be a case that a woman could diagnose and determine herself the condition that you have described? A —She could not

Q —Would that case be a case for medical, mechanical or surgical treatment, in its origin, and throughout the history of the case? A —It would

Q —That is, you would use medicinal and mechanical means and possibly surgical means? A —I would

Q —In what stages of that disease would you use medicine? A —If, as I stated—

Mr Hough —That is objected to as incompetent, irrelevant and immaterial

The Court —It seems to me that the only important thing is to show that the doctor believes there are some disorders of women, that will show a symptom of pain in the back, and then give his opinion whether or not this hypothetical medicine, assuming that it is Wine of Cardui, will have any effect on it

To which ruling of the Court the defendants, etc., excepted

Mr Hough —I do not think that it is contended that Wine of Cardui will cure every pain or disease that a person might have

Mr T J Scofield —As far as that is concerned, I am objecting to any statement by Mr Hough as to what they claim or don't claim Here is their advertisement

The Court —Counsel has a perfect right to disclaim always

Mr T J Scofield —Yes, at the proper time, and under proper circumstances

Mr Hough —The point is that the inquiry should be based upon the literature which says that this medicine might be the medicine which would do the good It don't say that it would be absolutely

Mr T J Scofield —This is based absolutely on your literature

Mr Hough —It says it might be, don't it? You ought to base your question on that

Mr T J Scofield —Well, let us read it and see what it says there?

Mr Hough —Go ahead

> *Mr T J Scofield* —(Reading) "That is where the pain is, in the small of your back It is terrible, nerve racking and unbearable You just cannot work. Don't let it keep up Stop it Take a dose of Cardui, the Woman's Tonic Lay down for a short rest In a few minutes you will feel much better" You will feel much better, not might feel better
>
> 'Take Cardui regularly for a few days It will make all the difference in the world Keep it up till the pain is gone and you have got back your strength Won't you thank Cardui"

Q—Now then Doctor, having heard —

Mr Hough —Will you finish the rest of that?

Mr T J Scofield —I will with pleasure, if you care to have it read

Mr Hough —Why, yes

> *Mr T J Scofield* I read it to the jury (Reading) "Yes you will' Will what? Think Cardui as thousands of others have done and are doing every day Try this plan of treatment it may be just what you need"

Mr Hough —It says "It may be just what you need"

Mr T J Scofield —Sure

Q—Doctor would you consider the hypothetical solution which I have mentioned to you proper treatment for such a condition as that which you have described? *A*—I would not

Q—Would you consider, assuming that the hypothetical medicine and Wine of Cardui are practically the same, that Wine of Cardui would be a proper scientific treatment for that condition *A*—It would not.

Q—Would you think Doctor, that the hypothetical solution or Wine of Cardui (assuming that they are practically the same) might be just what was needed for such a condition as you have described?

Mr Hough —One moment Do you mean the pain in the back?

Mr T J Scofield —The condition that you have described?

Mr Hough —I object until that is made more specific

Mr T J Scofield —The condition which produced the pain in the back, under the conditions which you have described

THE COURT —The objection will have to be sustained to that

To which ruling of the Court the defendants etc excepted

Mr Hough —We don't claim it will cure curvature of the spine

THE COURT —Ask the doctor as to whether this hypothetical medicine would be indicated for any kind of a pain in the back.

Mr T J Scofield *Q*—Have you an opinion doctor as to whether or not this hypothetical solution, and Wine of Cardui (assuming that they are practically the same) are indicated for any sort of a pain in the back such as has been described here? *A*—I have an opinion

Q—What is that opinion? *A*—That it would do no good

Whereupon the further hearing of the case was adjourned until 2 o'clock p m the same day, May 3, 1916

May 3, 1916, Afternoon

The court met pursuant to adjournment

TESTIMONY OF DR C HUGH M'KENNA (*continued*)

Dr C Hugh McKenna resumed the stand for the defendants He testified that he supplied to the attorneys for the plaintiffs the names of persons on whom he operated

CROSS-EXAMINATION BY MR HOUGH

Dr McKenna testified that the first case on which he operated came to him direct and had not been under the care of any other physician The second case was a ward case and had been under the care of Dr A A Small, who had been treating her for rheumatism Dr Small discovered the dermoid cyst and called in Dr McKenna to see the patient The patient had not complained of any symptoms other than flowing of blood from the uterus and of pain in the abdomen Dr McKenna was shown the picture of a woman with her hand on her back and was asked whether the location of the hand pointed toward pain due to menstrual disturbances or whether to the conditions which he described

Q—Well if a woman came to you and said she had a pain in her back and she put her hand down there would you first think of menstrual disturbance or would you first think of this tuberculosis of the spine or metastatic infection of the spine? *A*—I would think of all the conditions that I know that might cause a pathological condition of the spine

Q—You mean you would think of all of them at the same time? *A*—Yes just in a general way yes. I think that we are concerned with that situation in every case we see and we must necessarily take them all into account otherwise we are apt to run off at a tangent.

Q—Now is metastatic infection of the spine a very common trouble or is it very rare? *A*—It is common enough and I think I can describe that best by saying that I have heard in some of the leading clinics the expression used that those cases come in in crops

Q—Come in in what? *A*—Come in in crops

Q—In crops? *A*—Yes

Q—Is that because they are suggested by the Doctor to the patient or— *A*—It simply means that they come in large numbers. They come at definite periods of the year following certain infections that I described this morning—that inflammatory condition of that kind of the spinal vertebra may be caused by infection to the nose and throat and the fallopian tubes or the Bartholin glands, or the gall bladder infection, or appendix infection—any of those and, certain changes in the weather, and atmosphere is apt to stimulate.

Q—Well, what is the best crop season, Doctor, for that? *A*—I beg your pardon?

Q—What is the best crop season for that? *A*—As I said this morning—the question first is to determine—

Q—Well you said certain seasons of the year What is the best season for that crop? *A*—Well, I misunderstood your term when you said the best season I would say the worst season They come in as a rule shortly after the time that the crops are harvested and they come particularly from the farming communities, and it is supposed that the kind of work that is done on the farm all the lifting and bending and perspiring freely, and probably catching cold, has to do with the question of forming what we please to term as the locus minoris resistentiae meaning the point of least resistance, and consequently the infection, being present in some of those places is deposited in this point of least resistance which in these instances happen to be the joints along the vertebra

Q—Have you ever practiced in the country Doctor? *A*—No, I never have

Q—Are country doctors as a rule, prepared or equipped to handle cases like that? *A*—Country doctors—and I say this through my society connections — have done a great deal ever since I have been in medicine toward the question of perfecting themselves, so that they can take care of those cases in a scientific way There is not anything that I have described that they cannot carry out and are carrying out as far as I know, in most of the country places.

Dr McKenna was then cross-examined concerning the condition of the case in which the blood was flowing into the peritoneal cavity He stated that if the patient bled for a day or two she would probably be dead from hemorrhages He was asked to name other conditions producing pain in the back which were worse than those already named He mentioned carcinoma and sarcoma of the spine and crushed spine

PAIN IN THE BACK

Q—Well do you mean to say then that when a woman has a pain in the back she might have almost anything the matter with her? *A*—Well we must take the position as examining physicians that she might have any of these conditions and I would say that it is very essential that we take into account all of these things in order that we may not—although it might only occur once in a thousand times—miss that case which, if taken in the beginning, might be saved and a deformed spine saved

Q—Would you say that would be about the proportion in which those cases would occur once in a thousand times? *A*—No I would not say that I said even in the case that it only occurred in that proportion These cases occur much more frequently

Q—Well how much more would you say? Twice in a thousand times? *A*—I said that I believed—that I put it in a way that we could get a conception of it by saying that they come in in crops after the—particularly from the farming communities—after the harvest is over and I think that gives you a very good idea of the frequency particularly of the metastatic type of spine That is a condition of course that had gone unrecognized formerly and treated as lumbago and different forms of rheumatism and so on, until scientific medicines have put it on a very definite basis and—

Q—How late is that that it has put it on a definite basis? *A*—Well—

Q—Recently? *A*—Within the last ten or twelve years

Q—Now taking the cases coming in crops as you say what would the proportion be through a year? *A*—Well what way do you mean?

Q—Would the average—where a woman had a pain in the back—would there be one case in a thousand— *A*—Oh yes very much—

Q—Where it would be this metastatic infection of the spine? *A*—Yes it would be very much more frequent

Q—Two cases in a thousand? *A*—Much more frequent than that I should say

Q—Well give me an idea a hundred cases in a thousand? *A*—I—it is rather difficult because of lack of specific statistics at this time to say definitely what proportion of cases or what the percentage of spinal pathological—or what percentage these make of the pathological conditions of the spine but I would say that of the injuries or pathological conditions of the spine, that they are relatively frequent

Q—Well what do you mean by relatively frequent as many as ten in a thousand? *A*—Well I would say much more frequent than that—

Q—As many as— *A*—I do not know that I can give you the percentages

Q—You would say—

THE COURT —Mr Hough, I think the witness has made it pretty plain that he has no general statistics to go by He does not know the number of women in the world that have backache, and he cannot know the number of people that have these particular disorders of the spine

Mr Hough —How can he say it is general then?

THE COURT —He has told you in general terms Now, there is no use trying to get down to specific terms, because the witness says he cannot give them

Mr Hough *Q*—Do you say you are unable to give the percentage of cases? *A*—I said very definitely I could not give the percentages and I doubt very much whether there are any compiled statistics on that line of surgery, at this time

Q—As a matter of fact, is it not very rare with this condition, when a woman has a pain in the back, in comparison with all the other conditions? *A*—No, I should say it was not

Dr McKenna then stated that dermoid cysts are uncommon, relatively speaking Hemorrhagic cysts of the ovary are not uncommon Development of such growths might go on for a long time without the woman knowing anything about it Dr McKenna stated that physicians sometimes might operate thinking that a fibroid tumor was present when actually the patient was pregnant

Q—Do you know what is referred to as the Podsnapion plan of ignoring the function of menstruation? *A*—The which?

Q—The Podsnapion plan? *A*—No, I do not

Q—You say menstruation at puberty is always physiological? *A*—No, I do not say so

Q—In what percentage of cases would you say it is pathological? *A*—Oh, I would say probably in the neighborhood of fifteen to twenty per cent—something like that, in my experience

Q—Would you say that—or would you not say that amenorrhea, as a disorder of puberty, is very common? *A*—No, I would not I have so stated

Q—Is that stated upon your own practice and experience, or upon reading? *A*—That is based upon my own experience and my associations with other men in clinics, in a general way on my knowledge of such conditions

Q—Would you say it was based in any degree upon the experience of others who have written medical works? *A*—No, it is not based upon the—I said it was based upon my own experience and upon my association—as I learned it from other men in clinics

Q—Have you ever talked with Dr J Clarence Webster on that subject? Have you ever learned anything from him about it? *A*—I have talked to Dr Webster many times I do not know that I have talked to him specifically on those conditions

Q—*Doesn't he say it is very common?* *A*—*I don't know what he says*

Mr T J Scofield—I object to that question, if the Court please

The Court—Objection sustained

To which ruling of the Court the plaintiffs, etc, excepted

The witness stated that he had referred as a student to a book of Dr Webster on diseases on women but he does not know what the book states on this subject The witness was asked if he had ever read "Case Histories of the Diseases of Women," by C M Green of Harvard He does not know this book The witness has heard of hot gin being used for girls having amenorrhea or delayed menstruation at puberty He does not consider it a common remedy He would consider the alcohol in it as having a deleterious effect He does not consider alcohol as a food He is not familiar with the experiment of Atwood and Chittenden on this subject nor with Cushny's experiment

He has not read any editorial statement in the Journal of the American Medical Association as to the amount of alcohol which may be taken into the system in food without a deleterious effect but such a statement would not affect his opinion in any way The witness defined his belief as to what the pharmacopeia and National Formulary represent He believes that every patient should be treated as a patient and does not follow these books in prescribing

The witness does not remember that he has used fluidextract of cimicifuga nor that of cinchona

Q—Did you ever use the fluidextract of ergot? *A*—Yes, I think—yes, I know I have

Q—Well, you know that there is fifty seven drops of alcohol per dose in that, don't you? *A*—Yes I would say in that connection, that as far as the alcohol is concerned, that it has a deleterious effect, but, in order to get the effect of the ergot, over a certain period of time, we permit the deleterious effect of the alcohol to go on, in order that we may get the effect of the ergot, because it is given in conditions of flowing, as a rule, and in severe conditions where we must take that chance with it, but I should say that if the fluid extract of ergot was given, and the patient could go out and buy it and take it just as they wanted to, that I would condemn it just as much as I would any patent nostrum

Q—You mean that if the physician prescribes it, it is not deleterious, but if taken without the physician's— *A*—I do not say that at all I said that it was—that it has a certain deleterious effect, as far as the alcohol is concerned, even though the physician prescribed it, but I said, in order to get the effect of the ergot in that solution, we forego the deleterious effect, for a short period of time, because it is given under a physician's orders and directions, and is not given and left to the discretion of the patient

Q—Did you ever give tincture of cimicifuga? *A*—No, I don't think I have

Q—Did you ever give spirits of juniper? *A*—No, I do not think I have I may say, in that connection, that we are concerned more in finding out the cause of the disease, and we find that after we have gotten at the bottom or cause of the disease, and then the cause of medication is rather a simple condition

Q—When you say "we," what do you mean? *A*—I mean that in connection with my associates in hospital work, in a regulated hospital

Q—Are you speaking of the profession as a whole, or just of your associates? *A*—I mean that as these things are carried out in the larger clinical centers—the cross way roads physician can, too take those things up in a certain way—and that the best example of that situation is the manner in which the clinic has been built up here in Rochester, a little city of only 6,000

Q—Do you mean in Minnesota? *A*—Minnesota, yes

Q—Are you connected with Mayo brothers? *A*—No, I am not

Q—Do you refer—you refer to the Mayo brothers? *A*—I do

Q—Have you used the compound tincture of gentian? *A*—No, I do not believe I have ever used it

Q—Did you ever use tincture of hydrastis? *A*—I have used the fluidextract of hydrastis

Q—How many drops of alcohol were there in each dose of that? *A*—Well, that was immaterial, I do not know how much it was immaterial, because it was always given in a limited number of doses usually given in combination with the fluidextract of ergot.

Q—In combination with that? *A*—Yes, sir

Q—In combination with anything else? *A*—No, I don't think I have

Q—Each dose contains 45 drops of alcohol, does it not? *A*—It may be I said I am not a pharmacist, and I don't—

Q—You don't pay attention then to the— *A*—and I want to get the reaction of the drug—and, as I stated before, I am willing to forego the deleterious effect of the alcohol to get that, over a limited period, because I am watching that patient, and if there are any symptoms that lead me to believe that this is causing certain pathological conditions to occur—the deleterious effect, in different parts of the body—I immediately stop it

Q—You are talking about in your hospital work? *A*—Well, I would do that anywhere

Q—Before you got into hospital work Then you mean when you want to use a certain drug, you absolutely ignore the amount of alcohol that may be used with it? *A*—Well, I state that if I want to use a given drug I use it in such small quantities, as far as the amount of alcohol is concerned, that it will not produce any very bad effects

Q—But you say you do not know how much alcohol there is in it? *A*—Well, I know this, that if the amount would be used for a short time, that it will not cause any very bad effect

Q—Well, you know that in some you use as much as 115 drops to a dose don't you? *A*—No, I don't.

Q—What is the largest amount that you know that is in any medicine that you use? *A*—Well, if you will ask me the drugs that I have used, I will tell you the amounts I have used

Q—Well, you have used spirits of ether? *A*—In what way?

Q—Any way? *A*—I have used ether as an anesthesia

Q—Only in that way? *A*—That is all

Q—Compound spirits of ether? *A*—No

Q—Taraxacum? *A*—No

Q—Compound spirits of juniper? *A*—No, I have not used that

Q—Cannabis indica? *A*—I probably used cannabis indica

Q—Well, the main point is that you absolutely ignore the amount of alcohol, and you don't even know what there is in a dose, if you prescribe a certain remedy? *A*—I mean to say that the amounts that I give it in, and the length of time that I give it, that it would not have any deleterious effect, or, if it does have a deleterious effect, if it is noted, I would immediately discontinue its use

Q—You have used Warburg's tincture, have you? *A*—No, I do not think I have.

Q—Do you know what it is? *A*—I do not know it by that name

Q—Did you ever use bitter tincture? *A*—No, I don't believe so

Mr T J Scofield—Of what, Mr Hough?

Mr Hough—That is the name in the National Formulary, just bitter tincture

Q—Compound cathartic elixir? *A*—No, I don't think so

Q—Doctor, if you regard alcohol as deleterious in all cases, why don't you use a glycerin preparation of hydrastis or of ergot? *A*—Well, I may use them in some cases

Q—Have you ever used it? *A*—I may have

Q—Well, don't you know whether you have or have not? *A*—No, I don't recall—

Q—Don't you know that you never have used it? *A*—I don't recall I could not say definitely That would be a very difficult thing, Mr Hough, to say

Q—Why would it be difficult for you to recollect whether you used the one with alcohol, or one with glycerin? *A*—I think that would be a very difficult thing to state, when a man has been in active practice, and seeing a lot of cases in a large hospital over a period of twelve or thirteen years, just exactly what medicines he has used, that would be a difficult thing I said that I did not regard the amount of alcohol that I gave in a fluidextract of hydrastis or a fluidextract of ergot, over the period of time, even though it may be deleterious to a certain—to a slight degree—I said that I would forego the deleterious effect for the action of the drugs that were in the alcoholic solution

The witness defined the reason for his belief that the giving of alcohol in appreciable amounts for a long period is de terious, and he stated that to give alcohol to a girl at the time of puberty without any control would be vicious If it were controlled by a physician, the patient would not have an opportunity to form a habit The witness stated that from two to three years are required for the changes which the girl undergoes in passing from girlhood to womanhood—puberty He distinguished between what is normal and what is pathologic at that period

He stated that even in a normal condition there might be some pain during the establishment of menstruation He has even had cases in which, during the entire life of the woman, there was slight pain during the period and this was not considered pathologic and no medicine was indicated for it He stated that if there are chlorosis or anemia, medicine can be given

Dr McKenna stated that he had used viburnum prunifolium for about five years but that he got no effect from it either in tablet form or as fluidextract He does not consider it likely that something was left out in the tablet form which was in the liquid tincture or fluidextract He does not know if other physicians have reported effects obtained with this drug, but even so it would not change his opinion

The witness has treated cases of uterine displacements which were not operative cases He has used mechanical means but did not use any drugs by mouth with the idea that they would act on the condition If there was enlargement of the uterus, he might give ergot to contract it down Ergot is a uterine tonic If it was indicated he would prescribe an antiseptic douche He has used pessaries and he considers the following statement read from the Cardui Home Treatment as a truthful one

> No one should ever apply a pessary without the advice and under the constant supervision of a physician

Mr Hough *Q*—Well can't they be applied by a midwife or a nurse? *A*—I would say—my experience has been that if the pessary is_going to give the proper support it means that the uterus must be in the proper position, and the physician is the proper one to determine that

Q—Can you answer the question just as I asked it doctor whether it could not be just as well applied by a nurse or a midwife? *A*—I should say it could not

Q—Could not?

The Court—Or anybody else if they knew how?

Mr Hough *Q*—Or anybody else if they knew how other than a physician? *A*—I would say that nobody would know how as well as a physician

The Court—Well that is not the question If anybody knew how couldn t anybody do it? *A*—Yes anybody could if they knew how

Mr Hough *Q*—Then that sentence is misleading isn t it?

The Court—Well if it is you may so argue to the jury Mr Hough

Mr Hough—Can t I argue it to anybody else?

The Court—Not with the witness certainly

There are cases of pain in the back which may be treated by medicine and which are not operative The experience of the witness has been that the majority of cases should be treated by mechanical supports and by medicines The majority of cases which he sees are hospital cases which are classified in his service because they require a combination of mechanical and medicinal treatment

The witness does not remember that he has used wine of ipecac The only preparation of ipecac that he has ever used, was many years ago in connection with a cough mixture

Q—Now in cases of flooding that are not operative cases—first let me ask do you have any cases as a rule that are not operative cases or are the majority of your cases only operative cases now? *A*—I have a great many cases that come to me for examination and as I stated before that one of the real functions of my work is the question of going over those cases and getting at the cause of the trouble and I stated before that after the cause was ascertained that many of those cases were treated very simply even in a medical way and that as we have gone on in this scientific way the number of cases to be operated—

Q—Now will you explain what you mean by we right there? Do you mean the entire body of physicians, or you yourself? *A*—No, I mean myself and my associates in the hospital That the number of cases operated are less today than they were five and ten years ago because of the fact that we have better methods of determining the cause of disease

Q—You mean you don t act so quickly in the matter of performing operations as they used to? *A*—Yes that is right. In other words we determine the cause and we can definitely establish whether it is necessary to operate or not or whether the patient will get well without

Q—Well now, when a patient comes to you today, you not being in the general practice, and you decide that it is not an operative case, do you keep the case and treat it medicinally, or send it to another doctor? *A*—Well, that is determined entirely by the history and the examination, and all Those patients are ordinarily sent out to the hospital, and they are worked up there probably in combination with other men

Q—Then you keep them there after the examination, whether they need an operation or not? *A*—Oh, that all depends upon what the condition is It may be that in an office examination, after a history and all that you can determine definitely what that case is, and I may go on and treat the case myself

Q—You mean medicinally? *A*—Yes

The witness stated that he has cases of menorrhagia which were not surgical cases In the treatment he first determines what is a case of tuberculosis or case after pregnancy He believes that a large majority of the inflammatory conditions in the pelvis that cause menorrhagia are operative He has had cases of metrorrhagia which were not operative cases These were treated by mechanical methods but he does, if there is reason for it, prescribe medicines by mouth He may have prescribed viburnum prunifolium for that condition before he found out that it was inert and worthless

Q—Did your patients get well, any of them at the time you were giving them viburnum prunifolium? *A*—Oh, they may have and they might have gotten well if I didn't give them anything, but—

Q—Well did they get well while you were giving it to them? *A*—I found that in the majority of the cases that it didn't do them any good

Q—Did they get well when you were giving it to them? *A*—Well, I can t answer that question by saying that they all got well or that they didn t all get well I am stating that the majority of them were not affected by the—

Q—I am not asking you whether they were affected I am asking you whether the majority got well or whether the majority did not get well? *A*—The majority did not get any better by that form of treatment

Q—That is not the question Did the majority of them get better after you gave them that treatment? *A*—I stated that the majority did not

Q—Did not get better? *A*—Were not affected by the—

Q—I am not asking you whether that treatment did it I am asking you whether as a matter of fact they got better? *A*—I stated that they did not the majority

Q—They did not get better? *A*—That is why I discontinued it

Q—After using it for five years? *A*—I stated in a general way, as nearly as I can remember, that I used it during that period I never used it very extensively

Q—And during five years you continued using it without getting any good results from it or getting results which you considered were due to it? *A*—Yes in a general way I used it over that peroid during that time Of course I was developing the work in the hospital and was subjecting most of those patients to a more careful scientific scrutiny and was finding that if you determine the cause definitely, and all that it was possible to treat those patients very much better in that way than it was to try and give them any medicine

Q—Have you ever had any cases of dysmenorrhea which you treated by medicine given in the mouth which were not operative cases? Or cases which you thought required an operation? *A*—Oh I would say—I do not recall that I have treated many such cases I probably have seen and treated some cases that had a painful menstruation that was brought on by the question of a certain amount of congestion and any type of a hot drink would seem to do some good but I have felt that most—

Q—What medicines did you ever give? *A*—I beg your pardon?

Q—What medicines did you ever give? *A*—Oh, I have probably had them take a little hot brandy

Q—Hot brandy? *A*—Yes

Q—Anything else? *A*—No I don t recall Probably hot tea.

Q—Anything else? *A*—I don t recall of anything else

Q—And you probably gave viburnum for some of those cases too didn t you? *A*—I may have. I probably did, but it didn t do any good

Q—You are sure of that are you? *A*—Yes I am sure

Q—Did the brandy do any good? *A*—Well they probably thought it did

Q—Did you think it did? *A*—I didn t know But the fact that—do you mean to say the brandy?

Q—Yes. *A*—Why yes. I wouldn t mind if a patient were suffering with a dysmenorrhea that I knew was not organic in character I wouldn t mind giving that patient some hot brandy

Q—Did you ever treat any woman with medicine in the mouth during the menopause? *A*—Oh I suppose I have It all depends on the condition for which I was supposed to treat her

Q—Did you ever give her any brandy at that time? *A*—I don t know that I have.

Q—Did you ever give her any gin at that time? *A*—No I have not I have never recommended gin

Q—You have tried viburnum *prunifolium*? *A*—Well you are asking me just in a general way a lot of things that I have done and it is very difficult for me to answer that question unless you give me some specific reason for giving a thing Now if I have given medicine at the menopause—why I may have treated cases of conditions in the abdominal region anywhere, and given those patients medicine during the menopause Certainly I have

The witness was then asked as to the treatment of dysmenorrhea with drugs and also at the menopause He stated that he treated dysmenorrhea at the menopause just as he would at any other time If there was *only* discomfort, he would not give any medicine, if there was real pain, he would give something to relieve the pain He stated that it is his opinion that the hypothetical medicine would do just what it was assumed to do in the hypothetical question He was then cross examined as to the quantities of drugs in the hypothetical medicine

Dr McKenna reiterated that it was his opinion that in the quantities present the drugs in the hypothetical medicine would not produce their therapeutic effects which it was assumed they would have

The witness was repeatedly cross-examined as to his statement concerning his opinion as to points in the hypothetical question He stated finally that he does not know of any combination of the two drugs in the hypothetical medicine that would *accomplish anything*

The further hearing of the case was adjourned until 10 30 o'clock the following day, May 4, 1916

May 4, 1916, 10 30 o'clock *a m*

Court met pursuant to adjournment

TESTIMONY OF DR FRANK BILLINGS

Dr Frank Billings was called as a witness on behalf of the defendants

DIRECT EXAMINATION BY MR T J SCOFIELD

Q—What is your given name? *A*—Frank Billings

Q—You are professionally a physician, are you? *A*—I am

Q—I take it you are a graduate of some medical college or colleges? *A*—I am

Q—Of what, doctor? *A*—Why, I am Professor of Medicine in the University of Chicago and in the Rush Medical College and Dean of the Faculty of Rush Medical College

Q—Now, Doctor, may I ask you to talk loud, louder than you are talking, it is difficult to hear back here, and, if you will, speak a little louder, please *A*—I did not hear you I have not heard you quite

Q—I say, speak a little louder

The Court —You better be fair with the witness, Mr Scofield

Mr T J Scofield *Q*—What college are you a graduate of, Doctor? *A*—Northwestern University Medical School

Q—What year? *A*—1881

Q—Since your graduation, have you pursued your studies of medicine? *A*—I have

Q—Where? *A*—In Chicago

Q—Have you studied abroad, also? *A*—In the years 1885 and 1886, I spent those years chiefly in Vienna, Paris and London

Q—Have you had any *hospital* experience, Doctor? *A*—I have

Q—With what institutions? *A*—I was House Physician, Resident, at Cook County Hospital for eighteen *months in 1881 and 1882* I was Attending Physician at the County Hospital for about ten years, about 1890 to 1900 I was Attending Physician at the Mercy Hospital from 1888 until 1898 I was Attending Physician at St Luke's Hospital about ten years, I have forgotten the exact dates, and Consulting Physician of St Luke's Hospital until last year, from the time I retired as Attendant I have been an Attending Physician, and still am, of the Presbyterian Hospital, since 1898

Q—I did not understand what your connections are as stated by you, *with the* Medical Colleges at the present time Please state them again *A*—I am Professor of Medicine at the University of Chicago, also Professor of Medicine at Rush Medical College, which is a part of the University of Chicago, affiliated with it, and Dean of the Faculty of Rush Medical College

Q—Now, in your work, Doctor, do you give any special attention to any particular department of medical practice? *A*—I devote my time chiefly to what we call internal medicine That means, general diseases, as a whole, with diagnosis In other words, I exclude as a rule, from any treatment, the so called specialties and surgery I diagnose, devote my attention partly to diagnosis in the whole *field*

Q—Where you speak of diagnosis, will you tell us what you mean by diagnosis? *A*—By diagnosis, one means the recognition of the morbid conditions in the human individual, which cause the symptoms of disease

Q—Now, Doctor, in making a diagnosis of a condition, what is it that you do? *A*—We usually first obtain the account of the patient, or, if the patient is not able to give it, of someone who is acquainted with the conditions from which the patient has suffered In other words, the history, the past history of the patient, which includes always the symptoms as the patient has observed them himself

Next a physical examination is made of the patient, and that physical examination is supplemented—if necessary—by laboratory examinations of the blood, of the urine, if necessary of the stools, or if the individual happens to have suffered from something in which there is a fluid in the joint or in the chest, that is sometimes withdrawn and examined in the laboratory That is what we call a general examination

Q—Doctor, are you familiar—you use medicines, of course, in the treatment of disease? *A*—I do

WHAT IS A TONIC?

Q—Now, *are you familiar* with the action of drugs and of tonics? *A*—I am familiar with such drugs as I use

Q—What is meant by the word "tonic," Doctor? *A*—In medicine, the word "tonic" has practically two designations as we use the word In one sense the word "tonic" is used with the adjective "stimulating" a stimulating tonic, meaning that by the use of the tonic one would stimulate the functions, some of the functions of the organs of the body

For instance, a tonic for a muscle, would be one which would make the contraction of that muscle more firm than it would be *without the* tonic To stimulate the secretion would mean that one would stimulate, for instance, the juices of the stomach and make *more of them*, more of the juices to help indigestion or, in the case of excretions from the kidneys to improve or increase the excretions, *practically* secretions of the kidney

Or, for instance, to increase the nerve *tone Some remedies will act* upon the centers of the brain and spinal cord and improve the impulses, nervous impulses that go out Those *things we designate as stimulating* tonics

Then we have *another kind of tonic* which we call restorative A restorative tonic is one which adds to, as for instance—the best example would be with an *individual suffering* from a poverty of the blood, which we technically call anemia, and we give iron, an actual ingredient of the blood, and try to improve the quality of that blood Iron is a good example, *therefore,* of a so called restorative tonic

AMENORRHEA

Q—Doctor, we have heard *something in this* case about amenorrhea Will you tell the jury briefly what the term amenorrhea" means and what is the most common cause of it *A*—Amenorrhea — the actual derivation of the word means 'without menstruation," the absence of menstruation

When the menses fail to appear at the proper time or when they miss during the menstrual period of a woman, we call it 'amenorrhea," and the causes are various Certain constitutional diseases, with or without poverty of the blood, usually with poverty of blood, anemia, will cause it

For instance, tuberculosis of the lungs, or a general tuberculosis, is associated with anemia, and *one of the most common and early symptoms* of that is amenorrhea

People who suffer from diseases in which there is what we call secondary anemia — by that term I mean an anemia that is dependent upon some disease which is destroying the blood all the time, or is preventing the formation of new blood all of the time Those are called secondary anemias

As an example, malaria is associated with anemia because the parasite which causes malaria is in the blood stream, actually gains entrance to the blood corpuscle and destroys it Therefore anemia occurs

In the hookworm disease, of which we occasionally have an example in Chicago, imported from tropical or semitropical regions of the South, the worm sucks the blood from the intestine and commonly a bleeding occurs around the head of the worm, so that anemia is very common

Pellagra, a disease due to a faulty balance of diet, not enough animal food, as a rule, is associated with anemia, secondarily, want of nutrition

Bright's disease, one form of it especially, is associated with anemia, because the poisons in the blood due to the Bright's disease cause anemia

Then young girls in their formative period, as they are developing, will sometimes suffer from a want of general development of the womb, of the heart, or blood vessels, of the blood making organs, and they suffer from an anemia peculiar to them, and they do not menstruate

Those are the general causes, due to a want of blood, poverty of blood, or anemia, and amenorrhea occurs

Amenorrhea also occurs toward the woman's change of life, at periods sometimes extending over two or three years Sometimes the menopause will occur immediately, and sometimes it will take one year or two years, and I have seen it occur over three or more years in time in which the woman would miss for six *months at a time*

That is merely apparently the readjustment of the organs of her body to meet these new changed conditions, but that *description may* not meet it in some other woman, because occasionally she *menstruates* with the amenorrhea between That does not mean that that is associated with poverty of the blood It is *more directly* related to the nervous mechanism of the body, to the physiology of the body, and its physiological processes Does that answer in full, sir?

Q—I think it does, Doctor, sufficiently Doctor, are you acquainted with the drug known as cnicus benedictus? *A*—I am *not* acquainted with it from my own personal knowledge of the drug

EXPERIENCE WITH VIBURNUM PRUNIFOLIUM

Q—Well, are you acquainted with the drug known as viburnum prunifolium? *A*—I am

Q—Will you state your experience, if you have had any experience with the drug, and your conclusion as to its *therapeutic* value, if any? *A*—Viburnum prunifolium is the bark of black haw *It is drug* which has been known for a great many years It was — it has been recommended for many years by teachers of materia medica, the materials of medicine, and at one time recommended by specialists who made a study of woman's diseases, so that at one time it was *rather commonly* used, either in the form of what we call the solid extract of it, or the fluidextract of it

When used it at first was supposed to help stop hemorrhages from the womb It was supposed to help stop pain during menstruation It was supposed to tone up a good deal But, like other drugs that we had in our earlier days, proved out more therapeutically it has not to day the same standing that it had twenty five or thirty years ago or twenty or even fifteen years ago perhaps

Formerly it was prescribed a good deal by general practitioners and by specialists for these conditions that I have named, painful menstruation dysmenorrhea, or hemorrhage of the womb but it has gradually dropped out

I have used it myself either in the form of the solid extract—sometimes in the form of the fluidextract It is a nasty drug about one of the nastiest things that anyone can put in their mouth that is to taste almost nauseating in its effect, so that instead of using the fluid extract I have been in the habit of ordering the empty capsules in which the patient could put the 20 or 25 drops necessary to take three or four times a day as the case may be

Like all things it apparently sometimes had an effect in relieving pain in connection with what one was doing beside for painful menstruation It sometimes—the woman sometimes would apparently cease to flow to some degree while one was using it coincident with the use of other things but practically—I think I can speak for myself—

Mr Hough —I have difficulty in hearing you If you can talk a little louder, I would be obliged

The Witness —My own opinion is that it is a drug that has mighty small potency for the things for which we formerly used it

Mr T J Scofield *Q* —Doctor, do you still continue to use it? *A* —I used it this last year on one patient that is in 1915

Q —Now under what circumstances did you use it there Doctor? *A* —And I have occasionally prescribed it but very rarely, perhaps once or twice a year in recent years

Q —Formerly you prescribed it more often did you? *A* —In earlier years I did

The witness was then asked a hypothetic question as to his opinion of a hypothetic medicine similar to Wine of Cardui

Q —Now doctor what is that opinion? *A* —I would say it would have practically no effect upon a dysmenorrhea due to an anemia

Mr Hough —On which? *A* —Amenorrhea due to anemia

Mr T J Scofield *Q* —Why not doctor? *A* —Because it would have no restorative effect upon the blood

Mr Hough —Did you say restorative effect? *A* —Yes

Mr T J Scofield *Q* —Now doctor is there any single form of medicine or of medicinal treatment, a single form of it that would be applicable for an anemia which is due to such a very large variety of causes? *A* —No there is no single remedy that could be applied to all of the different types of anemia which I have named a moment ago

The Court —You have used the word anemia in your question and I am sure that you mean 'amenorrhea I think the reporter ought to correct it

Mr T J Scofield —Yes

Mr Hough —Which way did the witness understand it?

The Court —I do not think there is any doubt but what the witness understood it, Mr Hough

Mr T J Scofield —Now doctor in amenorrhea—

Mr Hough —One moment

The Witness —If I would substitute the word amenorrhea ' for the word anemia it would be the same answer

Mr Hough —The answer would be the same in either case? *A* —Yes

Mr T J Scofield *Q* —Now Doctor is amenorrhea which is due as you have described very frequently to anemia properly treated by any one form of tonic? *A* —No

Q —Why not? *A* —Because of its various causes and the treatments must be based upon the underlying causes

TREATMENT OF ANEMIA

Q —Now in treating anemia let me inquire whether or not iron and arsenic and strychnin would constitute good treatment. *A* —Iron is one of the chief drugs which we use because the blood contains iron in its corpuscles Arsenic is used because it stimulates the bone marrow and other blood making organs to make more cells. Strychnin is not a restorative tonic It may be placed in these restorative tonics to stimulate nerve sensations or something of that kind but of itself it is not a direct restorative tonic It is a stimulating tonic.

Q —Now Doctor suppose that you had an amenorrhea that was a result of anemia or due to anemia and that the cause of that anemia is malaria as you have stated in your previous answers What would be the proper treatment there? Would iron be proper treatment? *A* —Not at the beginning One must get rid of the malaria first One must give the patient the remedies which will destroy the malarial parasites which are in the blood and in the spleen and in the bone marrow and elsewhere in the body before one can expect a restoration of the blood by means of so called tonics iron and so forth

Q —Well suppose now Doctor that you have an amenorrhea from an anemic condition and the anemia is due to hookworm as the underlying cause What would be the treatment which you would have to give under those circumstances or what would it be necessary to do? *A* —There it is absolutely necessary that one must get rid of the hookworms which are in the intestinal canal before any more blood is made that is before blood will accumulate in any quantity and the amenorrhea due to the poverty of the blood in that case would remain until one got rid of the hookworms, and built up the blood

Q —Now then, doctor suppose that you had an anemia that was due to syphilis would that require a special form of treatment or not? *A* —It would

Q —What would it require? *A* —Antisyphilitic remedies must be used until the patient is at least partly restored to health, to overcome the anemia which is not infrequently present in syphilis

Q —Now doctor, is the same thing true of all constitutional diseases that result in anemia? *A* —It is We sometimes are not able to overcome the constitutional disease and therefore we cannot then get rid of the amenorrhea Tuberculosis of the lungs as you know is very frequently a fatal disease and if the patient continues—if the disease continues to progress, the amenorrhea persists till death and all the remedies in the world won't start it.

Q —Now under such circumstances as that, doctor, that you have last referred to would it be good practice in your judgment to undertake to stimulate the menses by any means? *A* —Well it would do no good and it would be simply a question of the judgment of the doctor who did it—that would be all It would be a question rather of the judgment of the man who had the management of the patient. Inasmuch as it would be ineffectual, it would be pretty bad judgment in my opinion

Q —Now, doctor, would you consider viburnum prunifolium and carduus benedictus in an alcoholic menstrum such for instance, as in the hypothetical medicinal solution which I have described to you as a tonic in any sense? *A* —It may be a moderately stimulating tonic because of the amount of alcohol in it that is stimulating with its bitter principles—possibly it might be an appetizer I suppose that it is dependent somewhat, upon the palate of the individual who takes it But I would not consider it a restorative tonic in restoring anything to the body, blood or power or anything of the kind

Q —Are you familiar with the condition known as inflammation as it affects the generative organs of a woman? *A* —With several forms of inflammation yes sir

Q —Well now doctor when inflammation passes up through the uterus and involves the lining membrane of the fallopian tubes what name do you apply to that condition? *A* —The general term salpingitis, meaning an inflammation, of the fallopian tubes

Q —With reference to the escape of the product of inflammation or the discharge which results from it, do those products of inflammation ever become locked up in the fallopian tubes or in any of the other closed cavities of the body? *A* —They do

INFECTION OF FALLOPIAN TUBES

Q —Now have you had any special experience or given any special study to the subject of locked up septic matter in the various closed cavities of the body such for instance as the fallopian tubes? *A* —I have

Q —Well tell us about it doctor *A* —Such locked up material due to infection — by infection I mean due to pus bacteria to minute organisms—when locked up form what we call a focus of infection That is it is circumscribed it is held in, it cannot get out it is locked in

The fallopian tube is a tubular affair with an opening at either end one in the uterus, and one outside toward the general peritoneal cavity Those two openings may be closed and within that tube is this septic secretion going on and it may be small in amount or it may be large in amount. I have seen them swollen up to that size (apparently indicating a diameter of about three inches) as big around as a pear a large sized pear

In that condition when such secretion cannot get out the germs that are in them are apt to pass into the general circulation into the blood vessels and they may lodge anywhere in the body They may lodge in the joints and produce a type of infection of the joints They may lodge in the heart, and produce a type of malignant heart disease They may lodge in the blood vessels of the kidney and produce a type of infection of the kidney and so on all over the body But more particularly in the fallopian tube and there are two kinds of infection that are the worst to do that.

One is the germ that causes gonorrhea We call it the gonococcus That locked up in such a place as the fallopian tubes may escape into the blood stream and produce malignant heart disease as any practitioner—I have seen and I think one could say that any practitioner of wide experience has seen a fatal disease result as a rule

It may go to the joints and produce what is commonly known as gonorrheal rheumatism That is a wrong term to use It is gonorrheal joint disease it is not related to rheumatism at all It is a gonorrheal infection of the joints sometimes attended with pus in the joints a serious disease and painful prolonged for long periods of months and sometimes years crippling in its effects

Then in addition to that locked up in here it may suddenly leak out of the outer end of this tube and produce peritonitis a gonococcal peritonitis That is not an uncommon condition at all among children in public institutions.

In our public institutions even in our own state as high as 40 to 50 per cent. of the young girls that are in our public institutions have acquired gonorrhea and many of them suffer from this infection of these tubes and peritonitis and joint troubles and all of that

The other infection which is important of the fallopian tubes is tuberculosis Tuberculosis which either comes from the uterus or from the blood stream and lodges in the fallopian tube which becomes the center of a generalized tuberculosis It may go to the peritoneum this lining of this great cavity and infect it and we have what we call tubercular peritonitis or it may spread to the lungs or anywhere else in the whole body it may spread anywhere.

Now besides those two main things that I have named, any other kind of a germ that is pathogenic for man that is that will produce disease and particularly the kind of germs that cause pus There are several of those varieties. One of them grows in a chain and the word streptos means 'chain so we call them streptococcus becaus it is a little round ball Those produce pus and they are common, and where they get into the uterus or where they get into the fallopian tubes they produce pus there, and while that is common, it is not as common as gonorrheal infection of women

Gonorrheal infection of women is one of the commonest things that we have to meet It is almost a shame to mankind, the number of women that suffer from gonorrheal infection of those tubes I think that covers it, sir

AN ILLUSTRATIVE CASE

Q—Now, doctor, have you any special case in mind that you came in contact with recently, in your hospital work or otherwise, that illustrates the matters which you have just been describing? *A*—One meets this type of infection in women very commonly in the hospital practice in which this gonococcus infection, unknown to the woman many times, sometimes an innocent wife suffers from infection of the womb, infection of the fallopian tubes and infection of the ovaries—and with that infection the womb, getting bigger, will often take a malposition, usually backward, carrying with it the tubes and the ovaries, carrying them down with it, and they become inflamed and matted together

We have that very commonly, producing generalized symptoms, which are probably not necessary to name to you, simply naming that general thing

Recently, that is, within the last few months, I had a patient, a young woman in the Presbyterian Hospital, who had had this infection of the fallopian tubes and of the ovaries, secondary to a general infection coming from her head

The infection was in her tonsils, which had been removed at her home in Texas It was in her teeth in her jaws It was in one of these sinuses up here these little hollow places in our heads and, as a consequence she had a joint infection

The general infection had become so severe in her joints that some of the joints were ossified Some of her finger joints were ossified, so that she could not bend her fingers The knees and ankles were involved in it, so that she was unable to walk She was bedridden

In the examination of that woman, it was also found that she had this pelvic condition, the matting together of these tubes and ovaries and that she suffered also from menorrhagia, and excessive flow The excessive flow was of such a degree that she was anemic, that is, had poverty of blood The cell count went down to about three million, where it should have been four and a half or five millions, in a certain amount of blood The color of her blood—the hemoglobin, as we call it, was reduced from an average normal of 85 in the woman, to 35 with her, and she was weak and bedridden and almost helpless, almost a helpless invalid because of those general conditions

Necessarily her treatment had to be long to get rid of the joint infection which was the cause undoubtedly, the result—that in her pelvic organs and about her head

Finally, however, because the hemorrhage continued, and did not respond to any form of drug treatment to stop that hemorrhage, or to build up her blood, it forced an operation, and, in the treatment of that woman, she was the one that I gave the viburnum prunifolium to, without any result upon the hemorrhage

She had painful menstruation, it had no result there Even ergot, given under the skin, or into the muscles so as to get its intense effect, in addition to its use by mouth—a drug that is potent to cause contraction of the womb would not stop it

Finally I asked Dr Webster, Dr Clarence Webster, who is the surgeon for diseases of women in the hospital, to look the patient over with me, and advise what we could do for that womb, to stop the hemorrhage In his opinion, after the use of these drugs, such as I had given her, operation alone would relieve her

In the operation these conditions were found, and the cause of the hemorrhage was proved to be a hardening of the blood vessels that go to the womb, and in the womb itself, and so much were the walls hardened, that they could not contract to stop the hemorrhage Consequently there was an anatomical condition there, a condition of the womb and ovaries, under which that hemorrhage would have gone on until the girl would have bled to death, in all probability, and the only relief came from tying off those blood vessels, and removing one diseased ovary and both fallopian tubes because of the conditions in them

Following that, that girl steadily progressed toward health That operation was done a year ago tomorrow, the 5th of May In September she left the hospital, or sometime in August, and came back to have her blood examination, and in September her red cells had mounted up to nearly five million, four million one hundred thousand, or something like that, hemoglobin 85 per cent She had gone from 115 pounds in weight to 125, and while she had still this irreparable joint trouble in her hands, and some in her feet, she was restored to her friends as cured as anybody can be

Q—Now, doctor, having this hypothetical solution in mind, and assuming that it is taken three or four times a day, in tablespoonful doses for such a condition of pyosalpinx, or other forms of inflammation, or locked up infection, such as you have been describing, where the products of inflammation are enclosed in the cavities of the body, have you an opinion as to whether the use of this medicine will (quoting from the Cardui Home Treatment Book, page 13) "restore the patient to health"? *A*—I have

Q—What is that opinion? *A*—I think it would have no effect in the restoration to health

CURE

Q—What is your opinion as to the difference between the cure of a disease and the relieving of symptoms of disease? *A*—I think in the first place, that the word 'cure" is a bad one People are restored to health, or the near health The word "restoration" is a good deal better than to say "cured"

We assume a good deal if we say that we are the active agents in absolute curing We help toward restoration To palliate means to relieve the symptoms Palliation means simply to relieve one of suffering It does not mean at all that you have even restored the patient to health

THE PERIOD OF PUBERTY

Q—Do you recognize the condition known as the period of puberty in girls as a natural physiological development in their lives? *A*—It is

Q—Do you think a medicine, such as I have described to you in the hypothetical question, should be recommended for all girls during the whole period of puberty? *A*—I do not.

Q—Why not, doctor? *A*—Because puberty is a physiological and normal development in a woman, in a girl It is when she passes from girlhood into womanhood When it does not occur normally, there is some constitutional thing back of it that prevents that I named one to you a moment ago

Certain girls are defective in physical development The womb remains infantile, that is, like that of an infant The blood vessels, the heart and other organs do not develop the way they should, and yet that girl has the external appearance of being pretty nearly normal One would get at it, if you made a physical examination—that these things were at fault

But that girl will fail to menstruate and will fail to develop, because her genital organs have not developed nor her body developed at the period of puberty

Girls suffer, a girl at her time of puberty is just as apt to suffer from malaria, from hookworm disease or from tuberculosis—yes, God help us too many of them suffer at that time Puberty apparently does not develop

You have got to get at the underlying disturbing thing that prevents that girl from showing a normal physiological puberty That is the whole point No one drug, or anything else is going to meet it

Q—Now, Doctor, on the assumption that the hypothetical medicinal solution which I have described to you, corresponds to Wine of Cardui, let me read to you the following statement from the Cardui Home Treatment, published in 1912 and copyrighted by the Chattanooga Medicine Company I read from page 24 as follows

> Every girl should take Cardui at the time of puberty It can never do her anything but good"

What is your opinion, Doctor, as to the truthfulness of this statement? *A*—My opinion is that that is pernicious advice to go out to anybody I could paraphrase it in the terms of the street, as saying, 'Being done good"

PREGNANCY

Q—Now, let me call your attention to another paragraph from the same book, copyrighted in 1912, by the Chattanooga Medicine Company I read from page 26, at the bottom of the page, under the heading of "Disorders of pregnancy"

> 'No one need be afraid of taking Cardui during pregnancy Its action is gentle and strengthening, and it can never do anything but good"

Assume again, Doctor, that the hypothetical medicinal solution corresponds to Wine of Cardui What is your opinion in reference to that statement? *A*—That again it is bad advice A woman in pregnancy is fulfilling again a physiological function Unfortunately and rarely, she suffers some of the accidents of pregnancy She may have some faulty implantation of the afterbirth that might make hemorrhages

Unfortunately, a woman that is pregnant sometimes has Bright's disease develop, a horrible thing Sometimes a woman gets, because of the pressure of the womb upon the tubes that run from the kidneys, the ureters—will get stagnation of the urine and will have infection of one kidney and pass into chills and fever in consequence

Sometimes a woman pregnant has already a disease She has heart disease from some old rheumatism—old heart disease from a past rheumatism—or she has tuberculosis, or she has malaria

She is subject to disease as any other woman But, with these exceptions that I have named, anywhere from 90 to 95 per cent of the women pass through pregnancy without any disease They suffer some, as women alone can bear suffering but it is the natural state of motherhood that she is suffering and if she is suffering that way she takes many simple remedies.

That mother is delivered in 90 to 95 per cent of the cases normally, and by that word "normally" I mean without any interference with the labor as an instrumental delivery, and she is delivered without injury to herself or to her child

That is normal, and 90 to 95 per cent of women pass through their pregnancy without any abnormality, and are delivered normally Therefore I answer the question that, to take any medicine—I don't care what it is—because it can do no harm, and will always do her good, is absolutely bad.

PAIN IN THE BACK

Q—Doctor, I read from the Ladies' Birthday Almanac, published by the Chattanooga Medicine Company, the 1913 edition I read from page 3 "Right there." There is a picture of a lady standing erect with her hand on her back (Pamphlet shown to witness.)

Just look at the picture, *Doctor* (Reading)

> "That is where the pain is, in the small of your back It is terrible, nerve racking and unbearable You just cannot work Don't let it keep up, stop it Take a dose of Cardui, the Woman's Tonic Lie down for a short rest In a few moments you will feel much better Take Cardui regularly for a few days It will make all the difference in the world Keep it up till the pain is gone, and you will have got back your strength Won't you thank Cardui? Yes you will as thousands of others have done, and are doing every day Try this plan of treatment It may be just what you need'

In the same Almanac Doctor I read from page 27

> "Those dizzy spells Liver trouble is the cause mostly of those dizzy spells It also causes nausea or sick stomach and bad breath yellow eyes and complexion Headache Constipation, chills and fever, rheumatism indigestion, and similar symptoms When your liver is wrong you cannot be right. It is the largest organ in your body"

I read from page 27—

Mr Hough —Have you finished that?

HEADACHE

Mr T J Scofield —I see that it relates to black draught and that is not the quotation that I desire. Omit the last Doctor which I have just been reading to you in regard to those dizzy spells. I now read from page 27

> "Oh that headache. Of course headache is only a symptom but it is a mighty miserable thing to have and when it becomes a regular visitor it begins to be a calamity
>
> 'Wine of Cardui will not act like a nerve deadener to kill the pain of headache but it goes down to where the real trouble is, and begins at once to remove the cause, the female inflammation irregularity or other form of womanly disease In this way after a few days the headache most likely disappears, and when the real trouble is cured it stops those regular visits Try the Cardui treatment for headache and other womanly pains'

Assume now Doctor that this pamphlet the Almanac of 1913 is printed in quantities of approximately twenty millions of copies, and is distributed to the women all over the country Have you an opinion as to what the effect of reading such a statement would be on women who are not suffering from any definite disease, but who may be influenced by suggestion?

Mr Walker —That is objected to

THE COURT —Have you finished your question?

Mr T J Scofield —Yes sir

THE COURT —He may answer

Mr Walker —"Have you an opinion of what women will think after reading that?' That is what the question amounts to

THE COURT —He is giving his professional opinion, that is all

Mr Hough —That is not his professional opinion at all That is not a professional opinion as to what a woman would think from reading that.

THE COURT —But what he thinks she would think is his opinion

Mr Hough —I know, but that is not his professional opinion

THE COURT —Based upon his experience

Mr Walker —If he has had any experience with women that have read that, that would be something in reference to that subject, but he has not and he is asking him now to pass on what a woman might think after reading it, which is something that is not even involved in the book

THE COURT —Why don't you change the form of the question, Mr Scofield? In the first place you have two extracts from the book, and they involve perhaps different disorders Why not separate them, and find out first if the witness has any opinion as to what effect Wine of Cardui would have for that particular disorder

Mr T J Scofield Q —Doctor do you have in mind the last excerpt which I read

> 'Oh that headache Of course headache is only a symptom, but it is a mighty miserable thing to have and when it becomes a regular visitor it begins to be a calamity Wine of Cardui will not act like a nerve deadener and kill the pain of headache right off, but it goes down to where the real trouble is and begins at once to remove the cause the female inflammation irregularities, or other form of womanly disease In this way after a few days the headache most likely disappears and when the real trouble is killed it stops those regular visits Try the Cardui treatment for headache and other womanly pains"

Now then Doctor assuming that Wine of Cardui is practically the same thing as the hypothetical medicinal solution which I called your attention to have you any opinion as to whether Wine of Cardui will do these things that are claimed for it in this excerpt, which I have just read *A* —I have

Q —What is that opinion? *A* —In the first place it assumes that the cause of headache in woman is a pelvic condition which is not true It may be a cause of headache but there are many others

It assumes that if a woman has pelvic disease—and I assume I suppose it assumes an organic disease—that it will remove that and therefore remove that cause of the headache with which I disagree

It is altogether bad because a woman is just as subject or more subject to headache from various causes as a man and if that headache —if she suffered from an organic disease that was removable that might be removed if attended to properly it would be absolutely harmful for her to play with medication applied to some part of her body which she thinks is the cause of her headache.

Bright s disease with the poison which comes from it is common to man and woman and headache is one of the most common symptoms of the severe intoxication of that disease fearful headaches No medicine you could apply would entirely stop it It may relieve by relieving the conditions temporarily of the poison in the body

Tumor of the brain, to which any of us are subject, causes pressure within the skull, and excruciating headache

There is a type of headache from which many human beings suffer, that is periodical People are sick at the stomach They are depressed physically and mentally, they have disturbed vision This is one sided often and therefore is called hemicranial, meaning half skull, or half side of the head That runs frequently in families They don't inherit the headache, but they inherit a nervous constitution which don t stand the wear and tear of life, and if they abuse themselves in any way, knowingly or unknowingly, they have some of those headaches

If they suffer from disease whether of the pelvic organs or of the kidneys, or of the stomach, or anything else If they have faulty vision If they have bad hearing, and have to strain to hear If they have trouble business or domestic If they overeat or if a man over smokes If a woman overdrinks tea or coffee, they have headaches The underlying cause always has to be approached and the remedies are nothing compared with the correction of the habits in that condition

So I could go on and talk to you for half an hour or longer about headaches of different varieties, to which all of us, including men and women are subject One must remove the cause, if it can be done, before one can relieve the individual permanently

We can palliate, we can relieve for the time being, a headache with various things But that does not restore the individual to a condition of health when he no longer has headaches That is mere relief, palliation

Q —Now Doctor have you an opinion, as to what would be the effect if any of such an excerpt as I have read here, if it should fall into the hands of a woman, by way of suggestion

Mr Hough —That is objected to

Mr T J Scofield —Well who had the underlying conditions which you have just been describing?

THE COURT —It seems to me the proper way to effect that is to have the doctor state what his experience has been with women in general as to what susceptibility they may have to suggestion Then, when you argue to the jury, you may apply the evidence in this case But Dr Billings of course cannot tell what any individual woman thinks, or what women in general think He may tell his experience as to the susceptibility of women to lend themselves to suggestion

Mr T J Scofield —Well, just answer the question, as it has been suggested by the court.

Mr Walker —May we take an exception?

THE COURT —Yes the point will be saved

To which ruling of the Court the plaintiffs etc. excepted

A —Women like all other parts of human kind, are apt to believe what they read and especially to believe what we read about health and disease It has been my experience that people will believe what they read in print rather than to believe someone who is absolutely qualified to tell them about themselves by word of mouth

Consequently, people reading of remedies of any kind are more apt to take them than if they simply heard of them by word of mouth and especially if in the wording of the remedy described many symptoms are enumerated, which may, like a shot gun hit something that individual has once in a while and they therefore will apply the remedy

Mr T J Scofield Q —Now, Doctor what would be the effect in your opinion of a woman taking a medicine containing the equivalent of 96 drops of whisky three or four times every day during pregnancy during puberty and during the menopause, with reference to the danger of causing the formation of an alcoholic habit? *A* —That would depend upon the individual. Some people will form a habit easily with any drug that affords any sort of a pleasurable or comfortable sensation Other people do not

The effect is also in a sense different upon different individuals A small quantity of alcohol, as much as named 48 drops three or four times a day may be of inestimable harm to some people and apparently another individual will take it for a long time without any perceptible effect upon him

To illustrate I have known—I had a patient under my charge who suffered from what we call hardening of the liver sclerosis of the liver who took one drink of whisky a day for years That is all he ever *permitted himself to take* and as I knew him intimately, I know he told me the truth

Sclerosis of the liver is an increase in the fibers in the liver until it shrinks down into a hard mass all covered over with little lumps like the hob nails of a shoe and it shrinks down until it no longer functionates, and the individual gets dropsy and dies

I have known also a man whom I had under my charge for years with his family who drank one quart of whisky a day for twenty years before he got sclerosis of the liver He drank whisky for years in enormous amounts

So that no one can say that taking a group of individuals that 48 drops of alcohol could not make a habit with that group of individuals It may It may make it in more than one. It may have harmful effects upon the stomach, upon the liver upon the kidneys in that group of individuals On some of them it may have no effect at all

But it is a bad thing to ask anybody, or a community of individuals or an individual to take a dose of alcohol or that amount of alcohol because it is surely apt to do damage to some of them.

Mr T J Scofield —That is all Doctor

(*To be continued*)

Correspondence

Treatment of Incised Wounds Involving Tendons

To the Editor —That the usual treatment of incised wounds involving tendons at their primary dressing is faulty is attested by the fact that a large number of fingers have to be amputated because of subsequent infection While a large number of cases are infected from beginning, a certain percentage become infected from improper handling under unfavorable surroundings There is abundant evidence to prove that the operating room is the place to suture tendons, and that only a limited number of cases are favorable for the immediate repair of the severed tendons

In my hospital service I have insisted that patients with these injuries be sent at once to the operating room, simply a sterile dressing being applied in the dispensary

Absolute asepsis in the handling of these clean tendon cases is the first requisite, for the delicate endothelial lining of the tendon sheaths has little or no resistance against invading organisms If the tendon is sutured in the face of any infection, or if infection subsequently develops, there is distinctly more loss of tendon and hence greater impairment of function than in cases in which no primary repair was attempted Although good results have been obtained in the primary suturing of tendons when done in the physician's office or the surgical dispensary, yet the fact remains that an unnecessary risk is taken, and the practice is to be condemned

Patients applying for treatment can be roughly grouped into three classes

1 Clean cases
2 Cases in which infection is liable to occur
3 Cases in which infection is already present

In all cases coming under Class 1, the physician should carefully scrub his hands and put on gloves before making any examination The surrounding skin is painted with 5 per cent tincture of iodin, the wound washed out with normal saline solution at body temperature, and a sterile dressing applied The part is dressed on a splint and the patient taken to a hospital for the repair of the tendons If hospital facilities are not available and the physician has to suture in his office, the same aseptic technic should be carried out as if the peritoneum was to be opened

Cases coming under Class 2 are treated in the same manner as those in Class 1, except that no attempt at suturing is done Also the patient is instructed to keep the parts soaked with a mild antiseptic solution If no infection occurs, suturing is permissible after seven days, the same rules holding good as in clean cases If infection does occur, the wound is kept wide open and the parts soaked for fifteen minutes in every hour in a weak antiseptic solution The various conditions arising must be cared for as they occur These patients have their secondary operation for the repair of the tendons in about six to eight weeks after the wound has healed

For those cases in which infection is already present, the treatment will depend largely on conditions found, the principal point being to supply adequate drainage Bier's hyperemia, wet dressing and rest will in the majority of cases assist in getting rid of the infection In these cases it is well to wait about three months after the infection has subsided before doing a secondary tenorrhaphy

Clean cases referred to me at the hospital are taken at once to the operating room, the dressings removed and the hand painted (wound excepted) with 5 per cent tincture of iodin The wound is gently irrigated with a mild antiseptic solution for about fifteen minutes Under nitrous oxid anesthesia the tendons are sutured, fine arterial needles and 00 catgut or silk being used To bring the torn flexor tendons into the wound, the hand is strongly flexed, for the extensor, strongly extended No instruments are used to grasp the tendons, and the practice of grasping the severed ends with hemostats is mentioned only to condemn it Two or three mattress sutures and one or two interrupted ones are used on the tendons The wound must be absolutely dry before it is closed If this is impossible, a few strands of silkworm gut are inserted to prevent blood clot The hand is dressed on a splint, in the case of the flexed tendons, over a rolled bandage so as to relieve tension on the tendons

GEORGE M DORRANCE, M D, Philadelphia

Exhaustion of the Supply of Ichthyol

To the Editor —Owing to the restrictions which the belligerent countries have placed on the shipment of drugs and chemicals to the United States, we have recently found it necessary to advise the drug trade that we can no longer supply ichthyol Ichthyol is manufactured only in Germany, from raw material found only in Austria We are the sole importers, and our supply has become exhausted You are aware, of course, that both national and state officials are at present engaged in prosecuting dealers in fraudulent substitutes for ichthyol

We believe that it is to the interest, not only of Merck & Co, but also of the medical profession, that this state of affairs should be known to physicians

MERCK & Co, New York

CORNEAL TRANSPLANTATION

To the Editor —In The Journal for April 29, p 1419, you say

> Recent improvements in the technic of corneal trans plantation have made this a useful surgical procedure in some of these conditions

Kindly advise me if you were referring to a particular operation that is successful in corneal transplantation or were making a general statement?

D W Stevenson M D, Akron, Ohio

Answer —The general operation of keratoplasty was referred to This operation would be justifiable only in selected cases in which the leukoma was extensive enough to cover the entire cornea, and in which an operation for optical iridectomy would not offer any prospect of success The original answer covered a lesion probably more extensive than it was intended to convey

EYE EAR NOSE AND THROAT JOURNALS

To the Editor —Please give me the name and address of all the journals published in this country devoted to the eye ear nose and throat.

Samuel Kennedy M D, Shelbyville Ind.

Answer —The following is a list of such journals

Ophthalmic Literature Majestic Building Denver Established 1911 Edward Jackson editor and publisher monthly $5

Ophthalmic Record 7 West Madison Street Chicago Established 1891; H A Fox publisher; Frank Brawley, editorial secretary monthly, $4

Journal of Ophthalmology and Oto Laryngology 32 North State Street Chicago Established 1906 Willis O Nance and Albert H Andrews editors and publishers monthly $2

The Index of Oto Laryngology 108 North State Street Chicago Established 1911 Joseph C. Beck editor and publisher monthly $5

American Journal of Ophthalmology Metropolitan Building St Louis Established 1884 Adolf Alt editor and publisher monthly $3 50

Scholarships and Loan Funds in Medical Schools

Official statements received from the various medical colleges show that of the ninety-five now holding sessions, forty-seven have provided free scholarships or loan funds, or both, for deserving students who are without means otherwise to procure a medical education In two instances (Alabama and Georgia) the scholarships are for residents of the state, but in the other colleges they are, with a few possible exceptions, open to all applicants These scholarships sometimes merely cover tuition fees, but most of them cover all fees for the year, and some cover fees for the four years A few furnish the student in addition with funds for part or all other expenses Altogether the reports received indicate that there are 296 scholarships in forty-two medical schools and that loan funds have been provided by eighteen medical schools It is quite evident, therefore, that no students who deserve to succeed need to be shut out from obtaining a medical education It is interesting to state that all but three of the institutions providing scholarships are high grade medical schools having been rated in Class A by the Council on Medical Education The colleges having scholarships and loan funds are as follows

SCHOLARSHIPS IN MEDICAL SCHOOLS

University of Alabama School of Medicine	66
Leland Stanford Junior University School of Medicine	3
University of California Medical School	1
University of Colorado, School of Medicine*	1
George Washington University Medical School*	2
Georgetown University, School of Medicine	2

Atlanta Medical College	12
University of Georgia, Medical Department	1
Hahnemann Medical College and Hospital, Chicago*	5
Northwestern University Medical School	9
Rush Medical College	6
University of Illinois, College of Medicine*	7
Indiana University, School of Medicine*	10
Bowdoin Medical School	1
Johns Hopkins University, Medical Department	7
University of Maryland, School of Medicine	6
Boston University, School of Medicine*	30
Medical School of Harvard University*	27
Detroit College of Medicine and Surgery	3
University of Minnesota Medical School*	1
Washington University Medical School	1

Vanderbilt University, Medical Department	4
University of Texas, Department of Medicine*	1
Medical College of Virginia	10
University of Virginia	2
Total in 42 medical schools	296

* Have loan funds also

† Has fifty or more scholarships for graduates of Philadelphia high schools

LOAN FUNDS

The colleges above which are marked by an asterisk (*) also have loan funds for deserving but needy students Such funds are available also at other medical schools, as follows

Yale University, School of Medicine, New Haven, Conn
Howard University, School of Medicine, Washington, D C
Tulane University of Louisiana, School of Medicine New Orleans
University of Nebraska, College of Medicine Omaha
University of North Dakota College of Medicine, University, N D
University of Wisconsin Medical School, Madison, Wis

Proportion of Physicians to Population in the United States

The accompanying table shows that the present proportion of physicians to population in the United States ranges from one to 365 in the District of Columbia to one to 1,217 in North Dakota, the average in the entire country being one physician to every 691 people In his report on Medical Education in Europe, Abraham Flexner showed that in 1912 the proportion of physicians to population in the German empire was one to 1,940, in Austria, one to 2,120, and in France, one to 2,834 In the table the figures regarding population are from the 1915 estimate of the United States Census Bureau and the totals of physicians are from the fifth edition of the American Medical Directory, just published The table follows

PROPORTION OF PHYSICIANS TO POPULATION

State	Population	Physicians	People to Each Physician
Alabama	2,301,277	2,569	892
Arizona	247,299	307	806
Arkansas	1 713,102	2,637	649
California	2,848,275	5,687	501
Colorado	935,799	1,733	540
Connecticut	1,223,583	1,678	728
Delaware	211 598	261	811
District of Columbia	358,679	1,482*	365
Florida	870,802	1,321	659
Georgia	2,816,289	3,421	823
Idaho	411,996	439	939
Illinois	6,069,519	10,648	570
Indiana	2,798,142	4,872	574
Iowa	2,221,038	3,751	592
Kansas	1,807,221	2,683	674

Duty to Discharge Persons Restored to Sanity

(Lawrence vs Barlow et al (W Va), 87 S E R 380)

The Supreme Court of Appeals of West Virginia reverses a judgment which dismissed habeas corpus proceedings instituted by the petitioner to secure his discharge after he had been committed to a hospital for the insane, and it orders his release Many witnesses were examined in relation to the sanity of the petitioner The physicians called by the defendants said that he had paranoia The superintendent of the hospital thought that he had been suffering from it since 1887 But it was said that this theory was repelled by the fact that he was in an insane asylum in Pennsylvania in 1887 and released as restored, that he was again in a hospital in 1895, and in an insane asylum in California for a period in 1902, and again released as restored, that he was not afflicted this way again until 1913, that during the lucid periods he was a good citizen and prosperous business man, that he was released on bond from the hospital in January, 1914, and his trial was had in November, 1914, and that he was out of the hospital about ten months without injury to himself From this undisputed history it would seem, the court says that the hospital physicians were mistaken in their diagnosis, or in the progressive nature of the disease But without discussing or calling into question the correctness of their theories, it was quite certain that there was abundant reliable testimony in the case to show conclusively that, if the petitioner was insane when he was committed to the hospital in 1913, he had been sufficiently restored at the time of the trial on the habeas corpus proceeding to make it improper to continue him in confinement. Should the theory of the hospital physicians prove correct, and the malady from which they said he was suffering progress until it should reach the stage that he would be unable to care for himself or his property, and it should become necessary for some one to care for him, then the hospital for the insane provided for such purpose by the state would be to him a haven of mercy, until then it would be a place of torment Under the code of West Virginia any person confined in one of the hospitals for the insane of the state as an insane person, "except in the case of a person charged with crime and subject to be tried therefor, or convicted of a crime and subject to be punished therefor, when in a condition to be so tried or punished," may be delivered to any friend who will give bond and security with the conditions mentioned in Section 10 of Chapter 58 If such person shall be restored to sanity while in the custody of such bondsmen, it is the duty of the persons having control of such hospital to discharge him from such custody and give him a certificate thereof If the persons in charge of such hospital fail or refuse to release such person from custody after reasonable demand, the writ of habeas corpus is a proper remedy to secure such release

Sufficient Evidence of Violating Medical Act—Instructions to Jury

(State vs Booher (Iowa) 155 N W R 167)

The Supreme Court of Iowa affirms a judgment of conviction of practicing medicine without a license The court says that the defendant contended that the evidence was not sufficient to show that he was guilty of violating the state medical act, or that he held himself out as a physician and surgeon, or that he publicly professed to cure and to heal, or that he made a practice of healing and curing The evidence was short The substance of it was that one witness went to the defendant's house for the purpose of ascertaining if the defendant would treat him for rheumatism, he said he did not remember what the defendant told him, but he took four or five treatments, the treatments being performed while the witness was lying on a sort of cabinet or bench and the defendant worked on his spine and legs The witness did not have any arrangement as to charges and never paid the defendant anything Another witness testified that the defendant came to his house and gave him a treatment This was done by an adjustment of some of the joints of the witness' spine He was stretched out on a bench which the defendant had brought with him This witness took three or four treatments and gave the defendant $5 A third witness said that the defendant treated his wife for goiter, treatment was administered by rubbing the goiter and rubbing the spine, the patient also had gas on the stomach, and the defendant rubbed the stomach She took twenty-four treatments, and for the services rendered to her the defendant received $20 A fourth witness testified that he had one of his arms out of place, that he had sought treatment without avail, and, finally meeting the defendant on the street, asked him to see if he could put his arm in place, which he did The court thinks the evidence was sufficient to take the case to the jury on the question as to whether or not the defendant assumed the duties of a physician, and that he publicly professed to cure and heal Nor was an otherwise correct instruction given to the jury erroneous because it omitted the thought, embodied in a similar instruction requested by the defendant, that it must be shown by the state that the defendant did publicly profess to be a physician, or surgeon, or obstetrician, and assume the duties of such, or that he made a practice of prescribing and furnishing medicine for the sick, etc These things are prohibited by the statute, but the statute provides that any person shall be held as practicing medicine, surgery or obstetrics who shall publicly profess to be a physician, surgeon or obstetrician, and it also provides that if a person practices medicine, surgery or obstetrics, or publicly professes to cure or heal, he is guilty, etc Neither was there error in a refusal to give an instruction which embodied the same thought and the further thought that the defendant did not tell the patients that he could cure or heal them An instruction was given that "the word publicly means openly, a declaration made in a public manner" while an instruction was requested by the defendant to the effect that the word publicly means "openly, a declaration publicly made, or in a public manner" There was no material difference in the two

Burden of Proof in Actions for Negligence

(Niebel et al vs Winslow (N J) 95 Atl R 995)

The Court of Errors and Appeals of New Jersey, in reversing a judgment recovered by the plaintiffs, holds that, in an action for damages against a physician for the negligent performance of a surgical operation, in that a gauze sponge was negligently left in the abdomen of the plaintiff, it was injurious error to charge the jury at the request of counsel that, If you find that the gauze was left in the abdomen of plaintiff and the incision sewed up by defendant or allowed to heal over it, the burden of proof is on defendant to show that it was not left there by any carelessness or negligence of his In an action of negligence, the burden of proving the negligence of the defendant is on the plaintiff, and, as a proposition of law for the jury's guidance at the close of the case, it never shifts to the defendant. This right of the defendant to have the plaintiff bear the burden of the affirmative is a substantial one, the denial of which is injurious error Neither the single fact nor the group of facts stated in the requested charge shifted to the defendant the burden of proof which, notwithstanding such facts, remained with the plaintiff The facts recited were a part of the plaintiff's case, in that they were steps in the establishment of the negligence of the defendant, the burden of proving which was on the plaintiff, the effect therefore of the request was that the jury was told that, if the plaintiff had established these steps in her proof of the defendant's negligence, the burden of exculpating himself from the complete charge of negligence was shifted to the defendant The practically injurious nature of the request will at once be apparent when it is remembered that in this case the operation, although performed by the defendant, a private practitioner, was performed by him in a hospital where he was assisted by trained, resident nurses, presumably *in the employ* of the hospital and familiar with their duties While the testimony was meager as to the precise nature of these duties it was infer-able from the evidence and from the terms "operator" and "assistants" that it was the duty of the latter at or just before the close of the operation to count the sponges in use, which at that critical stage the operator himself could not do without jeopardy to his patient The very meagerness of the proof and the fact that presumptions had to be met and inferences to be drawn made the question of the burden of proof all the more important, since it may well be that the state of the proofs was such that whoever had to bear the burden of proof must fail because of such burden In such a case the burden must remain where the law places it, or the resulting judgment must be reversed Nor was the injurious error of charging the plaintiff's request in any wise cured or rendered harmless by the fact that the correct rule had been stated to the jury in the body of the charge, for how was the jury to know which was the law?

The President, Dr William S Thayer, Baltimore, in the Chair

SYMPOSIUM ON SYPHILIS

Diagnosis and Treatment of Syphilis

Dr John A Fordyce, New York The future of the syphilitic individual depends on the early diagnosis of his infection and the intensity with which treatment is carried out in the first six months In the accomplishment of this purpose, the modern aids to diagnosis have rendered great service In primary syphilis, when the spirochetes are demonstrated and the Wassermann reaction is negative, it is possible to cure syphilis with salvarsan alone It cannot be determined how many doses are required It is better, therefore, to err on the side of safety and to give, at least, eight or ten doses and follow this with mercury for six months In secondary syphilis, when the early rash is present and the Wassermann reaction positive, it is better to precede the salvarsan with several injections of a mercurial salt, preferably a soluble one, on account of the economy of time In this way an effect is produced on the spirochetes, and when salvarsan is given the temperature reaction and an intensification of the rash, that is, a Herxheimer reaction, can be avoided After the salvarsan is begun the combined treatment is continued Salvarsan is given in doses of from 0 3 to 0 5 gm for men and from 0.25 to 0 4 gm for women at intervals of one or two weeks, depending on the tolerance of the patient Two or three such courses are given with rest periods of six weeks The mercurial injections are given every day if a soluble salt is employed, or once a week if an insoluble one My preference in case of the former is mercuric chlorid in courses of from twenty to thirty injections, given daily or every other day Of the insoluble preparations, gray oil (in the form of mercurial cream, of which 5 minims represent 1 grain), in series of ten to twelve injections, or mercuric salicylate (40 per cent), from 1 to 3 grains gradually increased, from ten to twelve injections constituting a course Each series is followed by a rest period of six weeks and then the procedure is repeated Wassermann tests are made periodically, but treatment is not interrupted in spite of a negative reaction until the adequate amount of medication has been given

We should keep in mind the possibility of involvement of the nervous system in secondary syphilis A complete record should be made when the patient comes under observation so that it can be compared with any subsequent developments In this way it is possible to detect the very earliest changes which manifest themselves objectively in the nervous system The most frequent are irregularity of the pupils, persistent headache, and optic neuritis or auditory disturbance In latent syphilis, with a positive Wassermann reaction, an investigation should be made of the cardiovascular and nervous systems or of previous involvement of any of the viscera, as, for instance, syphilitic hepatitis In cardiovascular syphilis or bone involvement, the prolonged use of mercury in connection with potassium iodid is probably of more value than the haphazard use of occasional doses of salvarsan The criteria of cure are a negative Wassermann reaction for, at least, a year, continuing so after a provocative injection of salvarsan, and a normal spinal fluid, with the exceptions noted

Treatment of Syphilis of the Central Nervous System

Dr Homer F Swift, New York The best treatment of syphilis of the central nervous system is the prophylaxis of syphilis, next in importance is the proper treatment of syphilis in the early stages No patient should be released from treatment until his cerebrospinal fluid has been normal, in so far as pleocytosis and the Wassermann reaction are concerned At times, there seems to be a slight excess of globulin which cannot be eradicated The problem is complicated by the peculiarities of the subarachnoid space, which is directly continuous with the perivascular, perineural and perineuronal lymph spaces Probably the spirochetes are carried along these channels, as the various lesions can be explained most easily in this way The plugging of these channels probably not only comprises the nutrition of the nerve cells, but also increases the difficulties of bringing the therapeutic agents in contact with the exudate. The separateness of the subarachnoid space from the blood vessels and general lymphatic system is well known Antibacterial immune bodies, vital stains and most drugs are not excreted into the cerebrospinal fluid Even drugs which act on the central nervous system when given by mouth or subcutaneously act in much weaker concentration when injected subdurally In many cases general treatment affects the course of syphilis in the cerebrospinal axis favorably, this is especially marked in the early forms of the disease The tendency of cerebrospinal syphilis to relapse has long been known, while the failure of tabes to respond to mercurial treatment has made therapeutic nihilists of most neurologists Even the marked improvement of most cases of cerebrospinal syphilis is often not followed by a parallel improvement in the cerebrospinal fluid

The desirability of subarachnoid therapy is evident The problem is to find some beneficial therapeutic substance which can be introduced repeatedly without injury to the delicate nerve tissue The preparations used today are (1) the serum obtained from patients shortly after intravenous injections of salvarsan, (2) serum to which small quantities of salvarsan have been added, (3) neosalvarsan in small quantities and weak concentration, and (4) mercurialized serum The direct application of mercury is theoretically of value There is, however, danger of repeatedly injecting mercurialized horse serum because of the liability to the development of a general anaphylactic state In the general treatment of syphilis of the central nervous system, if the patient shows signs of involvement of the cerebral meninges, or brain, salvarsan should be preceded by a short course of mercury to prevent the occurrence of a Herxheimer reaction in the region of the vital centers If the presence of gummas is suspected, a vigorous course of potassium iodid is of value In the meningitis of the secondary period, the response to alternate courses of salvarsan and mercury has been prompt and permanent in a number of my cases In the tertiary form of the disease, alternate courses of mercury and iodid and of salvarsan are usually followed by decided improvement The fluid should be examined before and after each course If it becomes normal after a few months' treatment, the prognosis is good

In tabes, because of the apparent sensitiveness to mercury, it is better to start the treatment with small doses of salvarsan intravenously, gradually increasing and giving an injection a week for six or eight doses If at the end of this course the Wassermann reaction is weaker, then a course of mercury may be tried, followed by another course of salvarsan If the reaction does not change appreciably, intraspinal therapy is of value The aim should be to bring the fluid to normal and keep it there This can be done in a majority of cases 75 per cent of our cases have a negative reaction with 1 c c of fluid, half of them have a negative reaction with 2 c c Fourteen of these remain negative with 2 c.c Only four have shown slight relapses Relapses in the fluid are usually accompanied by clinical relapses In only one patient with normal fluid have there been advanced signs of degeneration, in the presence of rapidly advancing tabes or of optic atrophy, it is desirable to introduce intraspinal therapy in addition to general treatment from the beginning The treatment of paralytic dementia has been disappointing, although the number of remissions and the amount of improvement under salvarsan and serum intraspinally is many times greater than the number of remissions in untreated paretics, and although occasionally the Wassermann in the blood and spinal fluid is negative the ultimate outlook is usually bad In the treatment of syphilis of the central nervous system the objects of therapy are threefold (1) the cure of disease, (2) the amelioration of symptoms, and (3) the prolongation of life With the possible exception of paresis, all of these objects may be obtained

Syphilis and Society

Dr Hugh Cabot, Boston At the outset of any attempt to estimate the value of reporting syphilis as a public health measure, it is necessary to distinguish between true reporting and false reporting True reporting requires that the case be reported to the health authorities by name and address precisely as are cases of other contagious diseases False reporting is reporting by number or by some quasisecret method The opinion of the public health officer is generally in favor of reporting The opinion of the practicing physician, and particularly of those physicians who deal with syphilis on a large scale has been almost unanimously opposed to reporting They reason that if physicians are required to report these patients by name they will in a short time have no patients to report. After a careful study of the question of reporting, I cannot avoid the opinion that it has been worthless as a method of assisting in the control of this particular variety of contagious disease Public opinion has stamped syphilis as a shameful disease, without sufficient justification, and has therefore driven these unfortunate persons into hiding Nine states have legislation which purports to make syphilis a bar to marriage, but in most of them the laws are such as to be absolutely worthless

To sum up the question of the benefit to be derived by reporting cases of syphilis to the public health authorities and the requiring of certificates for marriage, my opinion is this In the present state of public opinion the reporting of syphilis can have no scientific value in the production of statistics and can have no medical value in the control of the disease. Scandinavian countries have undertaken the wholesale treatment of venereal disease as a public undertaking, and though much difference of opinion exists in regard to the details I have heard no adverse opinion in regard to the principle Here, therefore, lies a most fruitful field of effort The state, the municipality and the university or corporation hospital must prepare to deal with syphilis on a large scale not only in regard to diagnosis but also with reference to treatment and subsequent supervision There is no reason why society should fear to separate a patient from the private physician The management of syphilis by the private practitioner has fallen far short of reasonable success in large part because the interests of the community can in no way be safeguarded If public or quasipublic institutions should offer as part of their hospital system thoroughly competent treatment of syphilis it can hardly be doubted that the public in general would at once take advantage of such an offer

Discussion on Symposium on Syphilis

Dr Isadore Dyer, New Orleans In a review of a large number of general hospitals it was ascertained by me that practically all of them refused admission to early or incipient cases of syphilis, that the ambulant case was generally not wanted and that all cases of syphilis as such, are accepted on sufferance The outdoor clinics everywhere show great preponderance over the cases of syphilis in indoor services, and where any statistics could be had, the clinics handled early syphilis almost always without the proper consideration of their danger to the community In spite of these facts, there are many hospitals which practice routine Wassermann tests for one or another reason, but apparently without any purpose directed to the control or prevention of the disease, so far as the early cases are concerned If every case of syphilis with a chancre, or with an early eruption, were hospitalized and treated under compulsion, the disease could be controlled far better than through any system of legislation regulating the report of cases or determining the eligibility of persons for marriage All general hospitals should have special provisions for the indoor care of incipient or acute syphilis, and all men who treat syphilis in public practice should encourage and enforce indoor care of such patients with the object of getting these subjects under proper control, and thereby minimize the spread of the disease Legislation should be directed at enforcing the hospitalization of cases of acute syphilis coming under public charge Educational movement should encourage the public to recognize syphilis as a communicable disease and amenable to isolation just as are scarlet fever, measles and other contagious diseases

Dr. Hugh T Patrick, Chicago I agree that the secret in treating syphilis of the central nervous system depends on early intensive and individual treatment The question is What treatment fulfils these requirements? The administration of mercury with potassium iodid will fulfil the necessary requirements in the majority of cases, provided enough mercury is given What is enough? Enough is to be determined by the results, and not by any given dose To the vast majority of men affected with syphilis one may give two huge inunctions a day without detrimental effect It takes as much as that to constitute adequate treatment of syphilis in man When mercury is given in these doses the mouth must be attended to carefully, which does not mean merely the use of any of the known mouth washes, but it means scrubbing the teeth and the gums thoroughly, three times a day, after the intelligent labors of a dentist have preceded In the majority of cases of syphilis of the nervous system, tabes and paresis subsequent administration of mercury or salvarsan is a matter of indifference and convenience In some cases experience shows that mercury accomplishes more than salvarsan, and vice versa Again, experience shows that some cases do best by alternating one and then the other As regards tabes dorsalis and paresis, a number of cases are incorrectly diagnosed as cerebrospinal syphilis or paresis The Lange gold test is not infallible for paresis

Dr Abner Post Boston Much trouble comes from the classification of syphilis as a venereal disease When we think of the accidental inoculations, of conjugal syphilis, of hereditary syphilis, and syphilis communicated in some other way, it is unfair to classify all syphilitics under the term "venereal" We ought to consider syphilis as a communicable disease and have it so recognized in hospitals and in reports of vital statistics

Dr William G Spiller, Philadelphia I am not a strong advocate of the intraspinal treatment of syphilis because I have had brilliant results in a number of cases by other methods It is possible to get brilliant results in cases of nervous syphilis provided the treatment outlined by Dr Fordyce is begun in the early stage of the disease It is impossible, however to get satisfactory results when destruction of nerve cells and nerve fibers has occurred The most that can be hoped for in such cases is an arrest of the pathologic process As to laboratory findings these are sometimes positive in the cerebrospinal fluid when there are no symptoms of syphilis of the nervous system These cases should be regarded as suspicious There are many cases which are probably late manifestations of syphilis in which the findings are negative

Dr George Walker, Baltimore In a recent examination of 1,080 patients, regardless of the diseases for which they sought treatment, 10 8 gave a positive Wassermann reaction In an examination of 327 prostitutes, 67 per cent gave a positive Wassermann reaction Of 480 inmates of an institution for the feebleminded, boys and girls, representing state charges, less than 3 per cent showed positive Wassermann reactions In an examination of sixty of the lowest grade of imbeciles there was only one that showed a positive Wassermann reaction

IMMUNIZATION AND ITS PRACTICAL APPLICATIONS

The Underlying Problems of Immunization

Dr Theobald Smith, Princeton The underlying principles of immunization are twofold 1 To prevent or to check disease by applying the methods copied from nature and improving on them in the interest of man, if possible 2 To discover the modus operandi of resistance to disease, the sequence of events which is associated with recovery on the one hand and with complete resistance on the other The object of immunization is to raise the resistance of the body The remarkable effectiveness of smallpox vaccination has left the impression that immunization toward any disease always means complete protection from that disease We miss here the quantitative concept which is involved in all life processes We must accept the fact that no kind of vaccination is invariably and completely protective We may, however, hope to convert a fatal into a nonfatal attack, a mild attack into one so mild as to remain unrecognized or into complete protection As long as the susceptibility of individuals varies toward the same infecting agent, we cannot expect the same treatment to bring all to the same level of resistance Nor is it possible with the same treatment to protect equally well against agents of high and low virulence To neglect the quantitative side of immunization is to bring the process into discredit because our claims cannot be justified One of the problems bearing on this phase of the subject is a better study of spontaneous mild disease as a result of exposure in the vaccinated individual and of attacks which may not be recognized by older clinical methods, and which even the patients themselves may overlook Our present conception of acquired immunity assumes that, after every exposure, there is some however slight, multiplication of the virus necessary to wake up the immunizing mechanism

The essential factor to be kept in mind is to raise such resistance with the least injury to the subject The direction which immunization is to take depends on the etiologic factors involved There are primary and secondary infectious agents in most diseases It is generally conceded that if we protect against the primary agent, the others are thereby kept suppressed The assumption underlying this view is that the secondary agents play no part in giving the primary agent an opportunity to infect, but that the reverse is true This, however, has not been proved When it comes to an actual outbreak of such a possible change of diseases, the situation is changed, the main or primary disease will run its course satisfactorily if the complications can be kept away The question, then, at issue becomes a choice of vaccine toward possible secondary invaders The general rule that a single attack of a disease protects for life is subject to many limitations All acquired immunity is a perishable commodity This question is complicated by several factors, among which are the following (*a*) The human body becomes more resistant to infection with age (*b*) There is a possibility of reinfection without clinical signs which will maintain and strengthen any immunity obtained in infancy and childhood

There is a clearly marked distinction between groups of micro-organisms as to the capacity of the host to be immunized experimentally With some the attempt is much more readily successful than with others Those bacteria which act only through their toxins are most easily kept in check by immunization Bacteria producing diseases of longer duration appear difficult to suppress in proportion to the chronicity of the affection To these general rules there are exceptions Endemic disease leads to relatively heightened resistance Since most of the diseases in question are due to parasites which survive and may persist in the blood during a lifetime, which, in other words, are able to subsist in an immune host, the most rational explanation is that based on the transmission of immune bodies to the offspring

Among the established facts in immunology is the greater efficacy of living virus over any other, the practical application of this fact, however, encounters many obstacles. There are the degree of permanency of the attenuation, and besides the attenuation of homologous viruses, the finding of naturally attenuated strains The preconception that strains of low virulence cannot immunize toward highly virulent strains should not stand in the way of actual trials Next to living virus, the bodies of bacteria killed by heat seem to have the best chance of producing immunity The success or failure of this method will depend theoretically on what is the important antigen If the aggressive activity or virulence of micro-organisms is rapidly lost after isolation from the tissues, the effectiveness of cultures killed by heat, or otherwise, will naturally depend on the total age of the cultures used, provided the factor of virulence is not completely destroyed when the bacteria are killed The evident success of this method in preventing an attack of typhoid fever is encouraging for this method of vaccination The relative efficiency of sensitized vaccines probably depends on a quantitative relationship between the antiserum and the bacilli For diphtheria toxin and antitoxin this can be controlled definitely It is difficult to see just how a similar accurate titration of immune serum and bacteria can be made in terms of any assignable units at present The only way open is to inject series of mixtures of variously sensitized bacteria and await results The explanation for the very effective immunizing power of sensitized toxins depends on the greater penetrating power of such mixtures The toxin appears to travel farther in combination with the antitoxin than when free Perhaps the last word in immunizing methods is the use, not of living or dead virus, but of distinctive parts thereof Theoretically, the attempt to find the chief antigen of a micro-organism and exclude all others as either unimportant or harmful is just as justifiable as the attempt to immunize the body toward the chief or primary infection, letting the secondary infection alone Of a series of antigens there may be one which represents the primary and, therefore, the most important aggressive or protective agency of the virus and which, if introduced in abundance, might produce that degree of resistance which later will interfere with the beginning of the infective process

The recent developments in immunologic research indicate that medical science is moving away from the doctrine that the toxins or poisons of bacteria are the chief substances against which immunization is to be directed That they are responsible for most of the injury inflicted must be granted, but the injury may be a side issue not in line with the main events The object of immunization is to suppress the invader, the problem underlying is to find the precise aggressive weapons which permit the invader to multiply The capacity of micro-organisms to enter and multiply in the tissues of the host may or may not be due to the direct action of the toxins If not, it would be useless to immunize them However, when we come to treat disease in actual progress, the neutralization of toxins may be a very important step

Serum Therapy

Dr William H Park, New York The advisability of using serums in any particular disease is influenced by a number of considerations The primary one is whether a serum is available which contains antibodies of suitable kind and amount to neutralize the toxins or aid the body cells or ferments in destroying the micro-organisms, others, whether the infection can be identified from clinical signs alone, or only after additional laboratory examinations, and whether the serums can be brought into contact with the toxin or organisms at the essential points in the necessary concentration and within the required time Dr Rufus I Cole believes that 75 per cent of all lobar pneumonia cases are caused by pneumococci of three strains which he has called Types 1, 2, and 3, and that the remaining 25 per cent are caused by a multitude of strains so numerous that in a moderate number of cases no repetition of the same type is likely to be encountered About 30 per cent. of the cases of pneumonia and about one third of the total deaths are caused by infections with Type 1 The results of serum injection seem favorable in Type 1, doubtful in Type 2, and absolutely negative in Types 3 and 4 The mortality up to the present time has been much less in the treated than in the untreated cases Serum sickness occurred in about 50 per cent of the cases, and while very annoying was not dangerous The serum should be standardized so that 0.2 c c of a recent serum will protect 100,000 fatal doses of a very virulent type of pneumococcus, and no serum should be put out that contains less than half that strength Cole advises 80 c c of serum diluted with 80 c c of salt solution injected intravenously, and repeated about every twelve hours until permanent improvement is noted Usually he gives from three to five doses He recommends that the serum be given only after the bacteriologic test has shown the type, while I believe that in a severe case a first dose of Type 1 serum should be given as soon as possible and the later injections only after a bacteriologic report

The treatment should be considered from two points, one the good of the patient, the other the advance of knowledge The severe cases that receive an injection of Type 1 serum are considered only from the first standpoint With the antistreptococcic serums the same reasoning applies as with the pneumococcic serums and the same dosage and method of administration If it is suspected that the infection is with the hemolytic type, we can rightly give this type of serum with the hope of some good results If we suspect the *Streptococcus viridans* type, a polyvalent serum of this type might be given with slightly less prospect of help Before giving further injections the organisms should be identified

In epidemic meningitis the spinal fluid in every case should be examined microscopically, for only in this way can a correct diagnosis be made Here, too, the strains differ, they have group relationships, and intravenous injection of suitably selected strains causes the horse to produce a serum capable of almost all strains The reports from England of failure to get good results under the serum treatment of meningitis may be explained by the great demand for the serum which leads to the attempt to replenish the stock of serum and which in turn leads to a too frequent bleeding of the horses, resulting in a serum which is found later to be poor in antibody content

I should like to refer to the favorable results obtained in the treatment of early toxic cases of scarlet fever with convalescent serum, or whole convalescent blood, by saying that from 100 to 300 c.c of fresh whole blood injected intramuscularly can also be used in acute and chronic exhausting diseases in which the nutritive and bactericidal value of homologous protein is distinctly indicated

As to the Schick reaction and dosage of antitoxin in diphtheria a single large dose of antitoxin has been shown to be more effective than a larger amount of antitoxin administered in several successive doses Were it not for the disadvantages inherent in the intravenous method, it would be the method of choice In patients who have been sick for from twenty-four to seventy-two hours and show a great extent of disease and symptoms of toxic absorption, from 3 000 to 10,000 units of antitoxin intravenously is imperative On the other hand, the mild or moderate cases may be treated by a subcutaneous or, better intramuscular injection

As to the methods of administering tetanus antitoxin experiments demonstrate conclusively the superiority of the intraspinal method

Dr. Ludvig Hektoen, Chicago, delivered an address on 'Vaccine Therapy," which was published in The Journal, May 20, 1916 p 1591

Discussion on Immunization and Its Practical Applications

Dr. Frank Billings, Chicago In chronic affections, both local and acute, more particularly the infectious arthritides, and in cases of furunculosis, alveolar abscesses, sinusitis pyelitis cystitis, etc we have attempted to carry out treatment by autogenous vaccines We tried to make our autogenous vaccines by the injection into animals of strains obtained from the tissues of man Furthermore we immunized the horse with polyvalent strains of the so-called *Streptococcus viridans* We had that serum standardized We used serum to sensitize vaccines of the type we are using We used serum in connection with the vaccines to attempt to arouse the defenses of the individual We have kept records of all of that work We have treated over 500 cases of chronic infectious arthritis, a number of cases of infectious endocarditis with *Streptococcus viridans,* a number of patients suffering from pyelitis, colon bacillus infection, and other infections While this work was going on, especially with the arthritides, I have attempted to see what could be done with the same class of patients without vaccines

Before we knew much of bacteriology or vaccine or serum treatment we recognized that certain individuals were more susceptible to disease than others because of exposure to cold to extreme fatigue, to any kind of mental or physical strain to poor general nutrition, and to many other causes Age in such cases plays an important part, and especially as to the resistance of the tissues and the possibility of tissue regeneration when once infected Alongside with vaccination we have attempted to find out conditions of that kind in patients and have sought by hygienic and other measures of treatment to remove them, and I find, so far as I can determine, that patients who had no vaccines with these general processes had their defenses aroused quite as quickly and fully as those who received vaccines If one did not pay attention to general hygiene and to the building up of these patients, the vaccines of themselves did not bring forth a response The use of autogenous vaccines in chronic processes, both local and general, is so limited that their employment has not justified the expenditure of labor and the price necessary to carry on the work That is a general statement, subject to modification that in certain instances, under certain conditions, and in certain individuals the use of vaccines seems to be of benefit, but take them as a class in general disease, I have yet to see the benefit of them

Vaccination, as practiced all over the country by the use of commercial vaccines, is a disgrace to the medical profession The fault is not to be laid at the doors of the people who manufacture these things, they would not continue to manufacture them if the doctors did not use them, and that is not the worst of it Not only do they manufacture them and put them up in polyvalent forms and advise them to be used in this and that way, but these firms make the diagnoses for the doctors and tell them when and how to use them The great trouble is that the average doctor is unthinking and unscientific enough to use a method of treatment which costs him but little thought, and he is so thoughtless that he disregards the results on his patients

Dr. Rufus I Cole, New York So far as producing immunity of any kind in an acute infection is concerned, we must keep in mind that the only evidence we have justifying vaccine treatment is the results which have been obtained by the experiments of Dr Gay and Dr Jobling From a study of the literature and from many experiments, it seems to me that there is very little justification for the use of vaccination in acute lobar pneumonia I have tried to produce active immunity in animals within a few days by various methods, but we cannot bring about that grade of immunity which one would expect to do any good within six or seven days In regard to serum therapy, here again we must be sure we have the same experimental justification for going ahead with any method of serum therapy The facts on which we can hope to justify any method of treatment are simply two 1 We cannot render animals immune or render them resistant to infection with the pneumococcus by treatment with living or dead organisms 2 By transferring the serum of the animals to the normal animal we can render the animal resistant, and, finally, we can, by transferring this blood to the animal which has already been infected, cure that animal, provided the dose of infection of the organisms is not too great, or that we have not delayed too long after infection In pneumonia I feel convinced that the use of serum in Type 1 infection, referred to by Dr Park, is efficacious That statement, however is based on a comparatively small experience When one considers the great frequency of pneumonia, with 6,000 deaths in New York City annually, 2,000 of that number being Type 1 infection, and Type 1 infection causing more deaths than typhoid fever, scarlet fever and all forms of meningitis combined, it seems quite important that serum therapy be given independent consideration

Dr Thomas W Hastings, New York For years specific therapy, particularly in the form of vaccine therapy, has been abused, mainly because care has not been taken to determine the specific factor involved This is just as important in using serums as in employing vaccines Discredit has been brought on the use of them because frequently specific diagnoses of the factors concerned are not made before serum is employed The day has come when the rank and file of physicians in this country should recognize the fact that it takes specialists to do this work, if it is done at all, and that the commercial use of polyvalent vaccines, without specific diagnoses, should be discontinued

2 **Operative Treatment of Varicose Veins of Spinal Cord**—The posterior spinal veins are sometimes considerably enlarged below the level of the spinal compression On account of interference by the pressure of an extramedullary neoplasm with the return venous flow, the veins become much enlarged and engorged with blood for a considerable distance below the level of the tumor When the cord of such a patient has been exposed, Elsberg says, one or both veins appear very large and very prominent, they are often more tortuous than normal In intradural inflammatory processes—meningitis and meningomyelitis—the cord has a pink color due to the fine network of distended arteries and veins in the hyperemic area The appearance is not the same as that below a spinal compression in which distended veins stand out prominently on the creamy-white background of the cord Therefore, Elsberg says, it is important for the operator to recognize and to understand the significance of these distended posterior spinal veins and to differentiate a venous engorgement due to pressure from an ordinary inflammatory hyperemia of the cord More or less localized enlargement or varicosity of one or both posterior spinal veins is a condition which is not very rare, it may be the cause of local spinal symptoms, and complete relief from the symptoms may follow an operative interference Among 130 laminectomies for spinal disease Elsberg has six times found one or several enlarged spinal veins on the posterior surface of the cord All of the patients had the signs and symptoms of a level lesion, and the greatest or only enlargement of the vein was found at the part of the cord which corresponded with the symptoms Two of the patients suffered from severe root pains and large veins were found to accompany the affected spinal roots

Elsberg believes that it is fair to conclude that there was some connection between the enlargement of the vein and the cord symptoms The enlarged veins were excised Of the six patients, two had a spastic paraplegia with sensory level symptoms of long standing, and their condition was unchanged after the operation One patient with a tuberculoma of the cord improved very much, but the improvement was due to the removal of the growth A patient who had suffered from severe root pains confined to the distribution of the left eighth dorsal root, and in whom a much enlarged vein ran with the root, was entirely relieved by the laminectomy and excision of the large vein Two patients were suspected of a spinal tumor, but nothing excepting the localized venous enlargement was found at the operation Both of the patients had well-marked sensory and motor signs, and marked improvement followed the surgical interference One of the patients recovered entirely

3 **Rôle of Sympathetic System in Abdominal Diseases**—The incidence and distribution of pain produced by disease affecting the abdominal organs supplied by the sympathetic nervous system is discussed thoroughly by Binnie "Reflex pain" and "referred pain" are analyzed from the anatomic basis He says, for instance, that the complexity of the nerve connections of the viscera, the perfection attained in the fulfilment of their vegetative or automatic functions, and the rarity of the higher centers being given cognizance of what is going on in the digestive tract, apart from a feeling of well being or satisfaction, excuse if they do not explain the confusion in the differential diagnosis of such distinct anatomic entities as appendicitis, pancreatitis, cholecystitis, gastric and duodenal ulcers "Referred pains" may be simulated closely by other very important pain Inflammation extending from the organ primarily involved may of course come into a region supplied by spinal nerves and thus pain result, such as the lumbar pain experienced in cases of retrocecal appendicitis, or the inflammation may spread to another organ adherent to that primarily involved, and thus a secondary "referred pain" may be noted An example of this latter condition is in cases in which an inflamed appendix becomes adherent to the prostate and gives rise to pain at the point of the penis In appendicitis pain may be experienced on the left side of the abdomen through direct extension of peritonitis or possibly, in the absence of such extension, by allochiria, because (Head and Howell), when from any cause one or other of the cutaneous senses is depressed in a given area stimulation in this region may give sensations which are referred to a symmetrical area on the opposite side of the body Impulses passing up from the ureter to the aortic plexuses may produce a disturbance there, sufficient to cause the transmission of motor impulses through the hypogastric plexus to the rectal sphincters and thus set up a tonic contraction Such tonic contraction is present in the cases in which renal colic is mistaken for obstruction

Binnie points out that originally the gastro-intestinal canal was a straight tube developed in the dorsal region and pushed into the primitive body cavity in such a fashion that it became enveloped with peritoneum but retained its connection with the dorsal structures by means of blood vessels and of nerves which lay between the layers of the primitive mesentery As development proceeded the various organs assumed the positions in which they are found in the normal individual The viscera ultimately normally take up positions which may be remote from the middle line, yet their telephone supply remains the same except for the necessary elongation of the wires Binnie suggests that this may explain why the early pain of most visceral lesions is generally median

4 **Pleural Exudate Caused by Typhoid Bacillus**—Pepper cites the case of a man who had been ill with fever and chills for three weeks He complained of no localizing symptoms, and on questioning admitted the presence of a slight pain in the chest for a day or two The temperature and pulse were elevated Physical examination revealed nothing abnormal other than the signs of a small effusion at the base of the right lung On aspiration a few cubic centimeters of hemor-

rhagic serous fluid were withdrawn, and from the cytology of this a diagnosis of pleurisy due to the typhoid bacillus was ventured This diagnosis was promptly verified by finding that both the blood serum and the effusion gave a positive agglutination test with typhoid bacilli and later by obtaining the *B typhosus* in pure culture from both the blood and the effusion

5 **Prophylactic Use of Tetanus Antitoxin**—It is held by Robertson that in the large majority of cases the subcutaneous injection of twenty units of tetanus antitoxin immediately after the injury will prevent with certainty the occurrence of tetanus The delay of a few hours in making the injection may mean the loss of life Local applications of fluid antitoxin on the wound are efficacious but unnecessarily wasteful and not always practical In cases in which injections cannot readily be made, especially in time of war, the immediate application to the wound of dried antitoxin tampons moistened by clean fluid may be used as a temporary substitute until fluid antitoxin can be injected, but powdered antitoxin on the wound is not, as a rule, dependable Its one useful field is perhaps the prevention of tetanus neonatorum The protection afforded by antitoxin lasts from two to three weeks Hence in cases of protracted suppuration or in cases in which for other reasons secondary surgical interference is contemplated, either second injections of antitoxin should be made or dried antitoxin tampons freshly moistened should be placed on the wound

6 **Localization of Cerebellar Tumors**—Grey's report has to do with the results obtained from using these tests in thirty-one patients with cerebellar or extracerebellar tumor The caloric test has proved to be an important means of differentiating labyrinthine from intracranial disease Together with the pointing reaction, this test has been found of value, furthermore, in localizing circumscribed lesions in the cerebellum In most of the patients having cerebellopontine new growths and in certain of those with tumors of one or the other hemisphere, the reactions were sufficiently characteristic to be of supplementary value in localizing the disease In other patients with intracerebellar or extracerebellar tumor, on the contrary, the results were often ambiguous and afforded no assistance in establishing a diagnosis In fact, in numerous instances the conclusions drawn from these results were at variance with the other physical findings, and, had any great reliance been placed in them, would have led to erroneous results Grey suggests that there are probably a number of factors responsible for the occurrence of atypical reactions in patients with certified cerebellar tumors As the more important he mentions first, the great increase in intracranial pressure due to an internal hydrocephalus which ultimately accompanies new growths in the posterior fossa, and second, the diffuse nature of many of the tumors common to the cerebellum

7 **Primary Splenic Hodgkin's Disease**—Mellon reports what he believes is the first case of the kind on record The entire clinical history covered a period of not over two years, the lymphatic glandular involvement of chest, abdomen and inguinal regions, all showed changes decidedly younger than those in the spleen

8 **Cholesterinized Antigens in Nonsyphilitic Serum.**—Nonspecific reactions were obtained by McClure and Lott with antigens representing additions of 0 0125, 0 0248, 0 0496, 0 0502 and 0 0996 gm of cholesterin to 100 c c of the alcoholic extract of syphilitic livers, also, with an addition of 0 101 gm of cholesterin to 100 c c. of the alcoholic extract of guinea-pig hearts The conclusion is drawn that cholesterin additions in the amounts above employed render the alcoholic extract more sensitive but somewhat less specific, and therefore of questionable value in the diagnosis of syphilis

11 **Time Relations of Gastric Pains**—Gastric discomfort of the intragastric and perigastric regions is divided by Friedman into continuous and intermittent varieties The continuous pains are most frequently due to carcinosis, to marked pyloric obstruction, and to penetrating ulcers, with peritoneal involvement. The intermittent pains may be divided into immediate, early and late The immediate are found frequently in ptosis, neurosis, obstruction of the cardia, besides other conditions, not considered here, as achylia gastrica, etc The early pains including those occurring fifteen to sixty minutes after eating, are most often due to adhesions in any part of the stomach, including ventral hernias and pericholecystitis These are to be thought of particularly in those cases in which the changes in secretion and motility are too slight to account for the distress complained of Late pains include those occurring one to three hours after eating, and indicate an increase in intragastric pressure or pylorospasm, of which the most frequent cause is hyperacidity It is occasionally due to slight pyloric obstruction or pyloric adhesions or reflex causes

26 **Studies in Alkalinity of Spinal Fluid**—Levinson believes that methyl red is the most sensitive and most suitable indicator for determining the alkalinity of the spinal fluid It is one of very few indicators that is sensitive to organic substances It gives a straw color to water, a strongly yellow color to alkaline and a bright red to acid The change from neutral to acid or alkaline is very sharp and can be used even for the determination of ammonia Levinson used 1 drop of a 2 per cent solution of methyl red in alcohol and adopted sulphuric acid for titration of the spinal fluid and that in one-hundredth normal solution He describes his method in detail The result of his study thus far seems to be that the alkalinity of the spinal fluid varies in different diseases The alkalinity bears a certain relationship to diseases of the meninges Furthermore, some diseases influence the alkalinity in a characteristic manner The determination of the chemical reaction of the fluid thus becomes of value in establishing the diagnosis of some forms of meningitis Fifty cases of spinal fluid were tested for its alkalinity, some of which were nonmeningeal in character, while others were true meningitis In nonmeningeal cases

the alkalinity varied from 1 5 to 2 6 c c Normal alkalinity varying between 2 0 and 2 4 In the meningeal cases the alkalinity was lower Epidemic meningococcus meningitis shows a lessened alkalinity of the spinal fluid Of 8 cases tested none reached to 1 5 c c the highest being 1 3 c c, the lowest 0 7 Pneumococcic meningitis also shows a lessened alkalinity from 0 9 to 1 1 c c, but tuberculous meningitis shows no decrease in alkalinity One case of influenza meningitis gave a 1 45 c c alkalinity The administration of serum had an increasing effect on the alkalinity of the spinal fluid

27 **Factors Affecting Incidence of Measles**—From a study of his own cases and a survey of the literature, Wilson feels that both the incidence and the case mortality rate of measles are subject to extreme variations and that the cause of these variations is not understood He says that cross infection, especially that of diphtheria, is the most serious event that can occur in the course of measles Suppurative otitis media, although the most frequent complication of measles, is not of grave prognostic import when properly treated Bronchopneumonia complicates about 10 per cent of all measles cases, being but little influenced by weather conditions in the frequency of its occurrence or its fatality The fatality of measles complicated by bronchopneumonia is 58 per cent, but this fatality varies in an exceedingly erratic manner and without marked relation to the total case fatality of measles The incidence rate of bronchopneumonia as a complication rather than its case mortality appears to be an index to the severity of any particular outbreak of measles.

35 *Methods for Testing Donors for Transfusion of Blood and Consideration of Factors Influencing Agglutination and Hemolysis G R Minot, Boston
36 Use of Duodenal Tube for Diagnosis and Treatment (To be concluded) F W White, Boston
37 *Gastric Ulcer Experimentally Produced by Means of Staphylococcus Organism, Preliminary Note E C Steinharter, Cincinnati
38 Fallacies of Group Treatment H J Cronin, Cambridge

35 **Testing Donors for Transfusion of Blood**—The various tests employed to test blood for its power to agglutinate or hemolyze other blood are described by Minot, including his modification of the Rous and Turner test, which he has found may be performed without the need of accurately diluting the blood by white counters, so that the disturbing factor of clotting is done away with Minot places 3 to 4 drops of a 1 5 per cent citrate solution in 0 9 per cent salt solution in a short (about 2 cm) test tube, with a relatively large diameter (about 1 cm), then collect in this tube 9 drops of blood from the recipient and one from the donor, and in another tube similarly collect 9 drops from the patient and one from the recipient The drops of blood are collected from a prick in the ear, trying to allow the blood to fall directly into the citrate, but it makes no difference even if the blood runs down the side of the glass The drops need not be of exactly the same size, and the amount of blood does not need to be accurate, but approximate After the mixtures have been mixed by shaking, and have stood for about fifteen minutes, take out a drop and examine it microscopically for agglutination

37 **Gastric Ulcer Experimentally Produced by Means of Staphylococcus Organism**—The organism used by Steinharter was obtained from a case of septicemia in man At first cultures of it injected intravenously into rabbits were found to produce a septicopyemia, but later, after cultivation in the wall of the living stomach of the rabbit, it showed on intravenous injection an affinity for the intestinal tract, locating most often in the appendix and occasionally in the stomach Typical peptic ulcers varying from one quarter of an inch to 1 inch in diameter were produced by injecting locally into the stomach wall the staphylococcus organism of certain grades of virulence and a weak acetic acid solution The injection of the organism alone usually caused the development of a small localized and firmly walled off abscess at the point of injection Such an abscess, as a rule, was absorbed in the course of four to six days and never showed any involvement of the mucous or peritoneal coats In some cases no abscess was formed The introduction of the acid alone into the stomach wall beyond causing more or less edema provoked no gross pathologic change in the tissues It never caused an ulcer, but it did seem to increase the susceptibility of the area for localization of the staphylococcus injected into the general circulation The tendency of selective localization in certain organs was found to depend among other things on the virulence of the organism and could be modified by cultivation in functionating tissue In the light of these results, it seems to Steinharter that it is possible that the staphylococcus is responsible for certain cases of gastric ulcer in human beings If by some means (through an erosion or trauma, etc), a hyperacid gastric juice enters the tissues of a limited area of the stomach wall and the staphylococcus of proper virulence (for example from the appendix) finds lodgment there, it does seem quite probable that the necessary conditions used in producing the experimental ulcer would be duplicated This point is still under study

55 **Gongylonema Human Parasite**—A specimen of *Gongylonema*, probably *G pulchrum*, according to Ward, has been recovered from man This species is normally a parasite of the pig Infection of the human host in Ward's opinion was brought about probably by the ingestion of larvae in the infective stage which had developed in some insect Very likely the croton bug, known by experiment to be able to serve as intermediate host for this species, was the source of the infection which might readily occur by accident The presence of the parasite was accompanied by clinical symp-

toms indicating marked digestive and nervous disturbances, associated with anemia These symptoms disappeared with the removal of the worm The parasite displayed a tendency to wander through the submucosal connective tissue from the lips to the throat

113 **Final Results of Colectomy**—In only six of the twelve cases operated on by Clark was the result entirely satisfactory In all cases there has been great improvement in the constipation for a time, to be followed at variable intervals in four by a gradual recurrence of the constipation In some cases this has not been so severe as formerly, whereas in others it is quite as intense Roentgen ray examinations in three cases showed in two decided dilatation of the ileum to a size closely resembling that of the colon In none of these cases has there been diarrhea of long standing, and none that was not controlled by simple medicinal measures In none of the cases has there been undue thirst In six cases there has been marked improvement in nutrition In the remainder there was no visible effects so far as physical improvement is concerned Clark feels that total removal of the colon is justifiable only in severe cases of obstructive constipation and that a less radical procedure must be employed He inclines to the limitation of the colectomy to the ascending and the middle of the transverse colon, with a lateral anastomosis of the ileum into the transverse colon In this way the omentum is preserved and there is far less traumatism to the mesentery, with its very important sympathetic nervous system The ileum will not uniformly assume the vicarious function of the colon and the backward pressure from the colon through the anastomotic opening, when it is low down, in a definite proportion of cases causes dilatation and permanent impairment of the ileum

117 **Effect of Foreign Substances in Peritoneal Cavity**—Cubbins and Abt claim that iodin is an intense irritant to the peritoneum and favors rather than inhibits bacterial action It will produce firm fibrous adhesions, either with or without any manipulation of the peritoneum Nor can they see the value of the use of ether in the peritoneal cavity and it is their opinion that individuals in whom it is used will recover

in spite of it and not because of it Petrolatum they found is an intense irritant to the normal peritoneum of a dog, and is absorbed very slowly, if at all They have had two cases of petrolatum in the peritoneal cavity of humans, in which it was necessary to open the belly and allow the petrolatum to escape practically in the same condition as it was when it had been put in three and four months before The walling off of the petrolatum in the belly of these two humans was just as firm as if it had been around an abscess Paraffin oil, too, is relatively nonabsorbable, and will not prevent adhesions, although it is far less irritating to the peritoneum than petrolatum Olive oil has little, if any, value in preventing adhesions, although it has little or no irritating effect on the peritoneum

120 **Sodium Citrate in Prevention of Peritoneal Adhesions** —Sodium citrate solution Straus found is of no value at all in preventing the reformation of adhesions which have been separated It is of little value, if of any at all, in preventing the primary formation of adhesions, and may interfere somewhat with wound healing

121 **Heterogeneous Intramedullary Bone Peg**—De Tarnowsky reports six intramedullary soup-bone peg cases in which he obtained good results Any of the long bones of a steer will answer the purpose For repair of a femur, the splint should be 4 inches long for transverse fractures, 5 or even 6 inches for very spiral or comminuted fractures, and approximately one-half inch in diameter, for the tibia or humerus 4 inches long and one-third to one-fourth inch in diameter *The splint is denuded of its periosteum, cut to the* proper size and boiled two consecutive days for two hours and one hour just before the operation At the time of the operation, it has been the author's custom to fit the peg to the medullary canal and not to drill the canal to fit the peg

124 **Dystocia Due to Ascites in Fetus**—This was a case of monochorial twins, one a well-developed female, the other, also a female, with failure of development of the pelvic viscera beyond a certain point and a marked edema Lynch and Jervey believe that the underlying factor in the maldevelopment and the edema was one of poor circulation with impoverished blood by reason of the stronger sister usurping the cream of the nutrition from the common supply or even bringing about a relative stagnation of the circulation in the weaker by reason of its superior power

12 New Forms of Plating Dishes for Cultivation of Bacteria S Delepine

4 **Treatment of Gunshot Wounds of Spine**—The position taken by Hull is that the majority of cases of gunshot injury to the spine require excision of the wound and exploration at the earliest favorable opportunity The diagnosis is not so gloomy as past experience teaches Local anesthesia is practically essential The administration of hexamethylenamin should be begun as soon after the injury as possible The presence of a missile together with severe pain are indications for immediate operation Accurate localization of foreign bodies is of the utmost moment A lateral as well as an anteroposterior view is desirable

7 **Fecal and Intestinal Vomiting and Jejunostomy.**—In all cases of paralytic intestinal obstruction (whether primary, or secondary to an organic obstruction or to peritonitis), when advanced to the stage of fecal, or short of fecal, intestinal vomiting, jejunostomy should be done says Bonney In all cases of obstruction, the stomach and jejunum will eventually be included in the fluid containing segment, and as soon as this occurs the fact is made patent by the change in the character of the vomit, which at first becomes intestinal and finally fecal This upward extension of the limits of the fluid containing segment is due to a rapid upwardly extending infection of the canal by organisms of the lower intestine This conversion by bacterial agency of the normal contents of the small intestine into a highly toxic fluid Bonney claims is the essential factor in the production of the symptoms of acute intestinal obstruction The presence of the toxic substances in the bowel excites the mucosa to exude a copious watery secretion which, mingling with the infected fluid already *there, itself undergoes* corruption Thus the upper intestinal tract becomes converted into a great toxic reservoir The death of the patient is due to the absorption of this toxic material, and the vomiting is Nature's desperate attempt to rid the organism of the poison It is here that surgery should step in and drain the reservoir and the drainage opening must tap the fluid containing segment

11 **Treatment of Diabetes**—For several years Hume has treated his diabetic patients by fasting, and cleansing of the alimentary tract, at the same time allowing a diet from which starch was not entirely excluded The fast is generally of about fourteen hours' duration The best time to commence is in the evening by a light meal about 5 p m and is followed in two hours by a dose of castor oil At 9 the next morning a second dose of castor oil is given and then no food for two hours By 11 a m the bowels have, as a rule, acted, and the patient receives breakfast There is, therefore, a period of absolute fasting between the two medicines In succeeding fasts salines are used, the object being to secure a thorough evacuation and to reduce the intestinal flora so far as possible. The patient can easily go through the same routine every second night, and after he has become accustomed to the treatment the duration of the fasts should be prolonged

by beginning earlier in the afternoon and extending them next day At the end of a fortnight a fast of twenty-four hours can easily be done two or three times a week If a small quantity of sugar persists Hume recommends two fasts each week of about fourteen hours, and finds this quite sufficient to prevent the other symptoms of the disease from manifesting themselves and to allow the patient to attend to his duties

21 **Treatment of Chronic Joint Diseases**—Grace has treated twenty-four cases of chronic joint disease by radiant heat and static electricity, with in a few cases electrothermic penetration (diathermy) also Among these were 2 ankle-joints, 11 knees, 7 hips, 1 phalangeal joints of hand, 1 elbow and 2 shoulders The ankles did fairly well, knees very well, hips uniformly badly, elbow-joints and finger-joints badly, and shoulders fairly well These results are obtained with a high candle power lamp giving at least 500 candle power from a single filament Grace uses 3 000 candle power and thinks it is better than the lower candle power lamp The static machine used should be capable of giving at least an 18 inch spark between prime conductors with one side grounded With suitable electrodes and a sufficient interval between contraction, very powerful and penetrating currents are tolerated In treating the knee, for instance, an 18 inch spark gap is borne with ease

31 Nervous Affections Consecutive to War Wounds of the Head (Au sujet des sequelles nerveuses des traumatismes cranio-cérebraux de la guerre d après une statistique de 256 cas.) M Villaret

29 **Test of Functioning of Vestibular Labyrinth**—Moure relates that, in addition to the usual tests, including induced nystagmus, he has found very useful a test based on a children s game The individual with eyes shut turns five or six times around a stick or cane which he touches with his head Then he opens his eyes and tries to walk straight forward The normal are unable to do this, always being propelled in the direction in which they have just been turning, and sometimes falling in this direction But when the labyrinth is more or less impaired, there is none of this propulsion, and the individual can walk off straight or nearly straight as soon as he stops turning and opens his eyes

30 **Carrel's Abortive Treatment of Infection**—Perret emphasizes that the success of Carrel's method depends on whether the wounded get the proper treatment within six hours Also that the wounds must be completely cleared out from all foreign matters before beginning the continuous irrigation with Dakin's hypochlorite solution He has applied the method in 111 cases of very severe wounds, including bones in 33 of the cases All the men recovered and amputation was not required in any case In short, he declares, with this method we are masters of infection of wounds Among the illustrative cases described is that of a man whose patella had been reduced to a pulp (*réduite en bouillie*) by a shell wound, the lateral ligaments alone not being completely severed The wound was cleared of bone and metal splinters and scraps of clothing, and Dakin irrigation kept up continuously The temperature did not go above 38 C. except on the day the drain was removed and the day the man got up There was no reaction in the joint at any time It was exercised from the twenty-second day on, he was allowed to get up after thirty-one days, and was discharged the fifty-fourth day after the wound, his gait, without support, absolutely normal

35 **Access to the Prostate Region**—Rochet discusses the various technics for this purpose, commenting on the narrow space available by way of the perineum, and the disadvantages by other routes He suggests as an improvement over them all, to mobilize *en masse* the entire perineum by separating from the side the middle fascia from its peripheral attachment to the entire ischio-subpubic triangle This releases the rigid support of the urogenital diaphragm which shuts off the small pelvis in this ischio-subpubic triangle He commences with Young s V incision The various steps of the technic are described in detail, and the advantages of the ample access afforded are extolled In two cases of cancer of the prostate he was much impressed with the facility of the *extériorisation énorme* permitted by this mobilization of the entire urogenital diaphragm

36 **Biologic Research on Wounds in War**—Forty-one articles on various aspects of military surgery were pub-

lished in the *Lyon Chirurgical* during 1915 and this number contains thirteen more Three are devoted to research on the biologic evolution of shell wounds, the general course, the initial proliferation of microbes, the natural curative processes, and the means to promote them Policard and Phelip demonstrate anew that the ulterior evolution of the wound is determined by what happens during the first four to six hours Substances to dissolve rather than to sterilize are needed at first, to clear the wound of mortified and dead tissues The dissolving action of hypochlorite gives better results later than measures to sterilize or tan the tissues The toxins absorbed from necrotic masses are responsible for the fever and collapse which develop before the germs have had a chance to proliferate much in the wound

Policard and Desplas report excellent results when they have ventured to suture extensive wounds without leaving the healing entirely to Nature There is always an inflammatory reaction, but it is usually insignificant and causes no general symptoms But it is always present, and always requires close supervision This is possible by repeated microscope examination of the serous fluid that oozes between the stitches It can be obtained with a pipet from quite a depth below the surface, and the microscope will show the defense the leukocytes are presenting and the increasing or decreasing numbers of germs A favorable sign is when the nuclei in the leukocytes take the stain intensely and seem to be more condensed and as if contracted

Leriche is convinced that mechanical cleansing of wounds and keeping them open to the sun and air are the ideals in military surgery Physiotherapy should supplant chemotherapy entirely as a rule, he reiterates

41 *Reaction to Vaccination Against Typhoid and Paratyphoid (Etude des reactions humorales dans la vaccination antityphoidique et antiparatyphoidique A B — serum de Vincent) Tonnel
42 War Wounds of the Chest (Les plaies penetrantes de poitrine par projectile de guerre) Piery To be continued

41 **Reaction to Antityphoid Vaccination**—Tonnel has been studying the reaction as 5,000 men were vaccinated against typhoid and paratyphoid, and he here summarizes the detailed findings as recorded with minute care in thirty healthy soldiers and in twenty who were already under hospital care There was always more or less of a reaction evident in the blood and urine, but in some of the men it was so exaggerated as to be actually pathologic He noted with surprise that the reaction was least intense in the tuberculous and those with albuminuria, while some of the apparently healthy responded with a pathologic reaction There is always more or less destruction of red corpuscles, a loss of half a million may be regarded as the average This suggests the necessity for caution in vaccinating persons known to have unusually fragile corpuscles Kidney trouble also calls for caution After the vaccination the urine becomes much less toxic His test for this was with infusoria placed in the urine They die in a few seconds in normal urine The reduction in toxicity may be estimated from the length of the survival of the infusoria With a pathologic reaction to vaccination the infusoria persist unharmed in the urine while the uric acid and urobilin content of the urine is much increased, and the red count is much less

46 Rat Bite Fever (Cas de sokodu — septicemie éruptive par morsure de rat — observe dans la zone des armees) J Fievez

45 **Acute Nephritis in Troops on Active Service**—Gaud and Mauriac state that of the 2,000 sick and wounded who passed through their hands in the course of three months last fall, 6 5 per cent had acute nephritis and the proportion has grown larger since Acute nephritis was a rarity during the early part of the war After from three to six days of lassitude, headache and pains in the lumbar region, the edema develops in the course of a few hours, the face generally puffing up first This nephritis runs its course like an infectious disease, with a rapid and cyclic course The fever at first, the extensive edema, high blood pressure, high albuminuria and traces of blood in the urine are its main features

Under the influence of repose and milk diet, recovery was the rule in two weeks in an average, no case lasted longer than four weeks No complications were noted except in two cases, these men were in coma when brought in and had had several uremic convulsions and the urine contained up to 8 gm of albumin to the liter Venesection twice repeated brought rapid improvement and recovery in one case but the other patient succumbed This has been the only death from nephritis in the service No drugs were used except a little theobromin The hardships of the campaign reduce the resisting power of the kidneys so that albuminuria is frequent among the apparently well soldiers When some infection happens along the kidneys bear the brunt of its attack In five of these nephritis cases bacilli resembling those of typhoid and paratyphoid were isolated from the blood or urine

58 *Ossification Process in Fallopian Tube (Zur Kenntnis der Knochenbildung in den Tubae uterinae) H Lehmacher
59 Fetal Ascites as Obstacle to Delivery (Geburtshindernis infolge von fotalem Aszites) J R E Meumann

54 **Young Human Ovum.**—An otherwise healthy woman died three hours after drinking lysol with suicidal intent and sections of the uterus revealed an embedded ovum of perhaps two to three weeks, one of the youngest that have been studied Colored plates show the details of its structure Most of the other specimens of the kind on record were from pathologic cases

55 **Treatment of Genital Tuberculosis**—Kröner reports *the present status of 25 women with genital tuberculosis for* which he operated from fifteen months to over four years ago Two have died since and the objective findings are not good in 5 others, although they feel well 18 are practically cured and have gained materially in weight, with earning capacity restored In his total 32 cases of genital tuberculosis in women in the last three years, the lungs were only slightly if at all affected in 3 The cases in which there had been perforation of the intestines, or tuberculous material had been left behind, gave naturally a less favorable outlook, and the course of the cases confirmed the gravity of such conditions The clinical picture of genital tuberculosis is often that of inflammatory processes in ovaries or tubes with extensive destruction of tissue and large collections of pus in ovaries or tubes or both The danger is great unless the whole can be resected But when both ovaries and tubes and the uterus down to the cervix are removed at a laparotomy this guarantees in most cases—when the genital affection dominates the clinical picture—a prompt and complete subjective cure with restoration of earning capacity and freedom from subjective disturbances The 32 cases described formed 14 per cent of his operative cases of diseased ovaries or tubes during this period Five of the women were between 15 and 20, and fifteen were between 20 and 30 One was over 50 Menstruation had been normal in 66 per cent. in 4 cases there had been amenorrhea for a few months, and in 2 there had been excessive bleeding In some cases there was no pain, in others much sacral pain and more or less abdominal pains All the women were ailing and weak, some actually confined to bed There was fever in 4 of the 21 cases of pure genital tuberculosis, and in 5 of the 11 with complicating tuberculous peritonitis Both tubes were always seriously involved Differential diagnosis is immaterial as the clinical picture of chronic disease in the uterine adnexa calls for a laparotomy regardless of its etiology If adhesions contraindicate excision of the focus, intervention must be limited to local medication of the abdominal cavity Kröner makes a point in all operations on the adnexa to wait until the temperature is brought down to normal before attempting to operate

58 **Ossification in Fallopian Tube**—Lehmacher has found five cases on record and adds two more to the list In his cases, the tubes had been removed from a married woman of 47 who had never borne children, and from the cadaver of a woman of 56 who had succumbed to heart disease Both tubes in each case were found obstructed with lime detritus around which bone had developed, with marrow

60 Sclerous Eczema (Das schwielige — callöse — Ekzem) P G Unna To be continued
61 *Prophylaxis of Tetanus (Die Erfolge der Schutzimpfung gegen Wundstarrkrampf) Kummell.
62 *Improved Technic for Roentgenography of Fistulas (Die radiologische Darstellung der Ursprunge von Fistelgangen mittels einer vereinfachten und verbesserten Fullungstechnik.) G Holzknecht L Lilienfeld and F Pordes
63 *Connection Between Tonsillitis and Articular Rheumatism, and Danger for Military Efficiency (Zur Kenntnis des kausalen Zusammenhanges zwischen Angina und Gelenkrheumatismus und deren mogliche Folgen auf die Wehrfahigkeit.) Brodzki

61 **Prophylaxis of Tetanus**—Kümmell has been making special inquiry in various German hospitals as to the occurrence of tetanus during the ten or eleven months since the wounded have been given a prophylactic intramuscular injection of 20 units of tetanus antitoxin as a routine measure In one hospital that had previously had numerous cases of tetanus the only case since among 700 severely wounded was in the one man who by some blunder failed to get his intended injection Among 1,555 severely wounded men, only one case of tetanus developed, but this proved fatal He has found that during the period in question, only 42 cases have been known in army circles, although the soil, the weather conditions etc., are practically the same as the year before when the disease was so prevalent Of this 42, only 7 of the men had received a prophylactic injection The incubation period ranged from five to twelve days Aschoff and Robertson last year reported a compilation of 66 cases of tetanus which had developed notwithstanding a previous prophylactic injection, 36 terminated fatally, but the injection was made very late in all but 18, and 9 recovered in this group of 18 Kümmell emphasizes further that according to all reports, the protection conferred by the antitoxin lasts for only fifteen days, and, if the wound is very much soiled only a week's protection can be counted on Hence it is necessary to repeat the injection a week later if any operative measure, even the slightest, is contemplated It is better, also, to repeat the injection before any operation for a person who has had tetanus, even though a long interval may have elapsed Kümmell concludes by warning that a few persons seem to be especially susceptible to tetanus infection, and that it is impossible to count on effectual prophylaxis for them It is also difficult to realize when tetanus germs are harbored in overwhelming numbers He cites the statistics in this country of Fourth-of-July tetanus as further testimony to the value of antitetanus serum prophylaxis As to treatment, he says that no dependably favorable results have been realized to date with any method of treatment for tetanus when it is once under way (See abstract 5 in American Current Literature Department, this issue)

62 **Roentgenoscopy of Fistulas**—Instead of bismuth paste, Holzknecht and his co-workers use cocoa butter bougies containing bismuth or other opaque substance, with a little antiseptic. The bougies are made 8 mm long and 2 mm in diameter, and they are easily pushed up into the fistula, one after the other, until the fistula is filled up The bougie melts from the warmth of the body and flows into the recesses of the fistula while the outer end of the last one, in contact with the air, does not melt and thus it plugs the orifice A wash button is fastened over it, with plaster strips, to hold it in place A number of roentgenograms are reproduced with the bougie filling and with the ordinary bismuth paste filling, clearly showing they say, the advantages of the former Bismuth paste is liable to run out and give misleading shadows

63 **Tonsillitis and Articular Rheumatism.**—Brodzki relates that among the 1,200 sick marines in the navy hospital in his charge in the seventeen months of the war, no less than 610 were cases of tonsillitis, and in 10 per cent of these articular rheumatism followed He expatiates on the importance of rendering the tonsils less permeable to microbes, and insists that every recruit with enlarged tonsils or history of tonsillitis should have the tonsils removed as a prophylactic measure, or at least they should be thoroughly seared to provide a cicatricial barrier against infection from all sides

72 Improved Counting Chamber (Eine Zählkammer für zytologische und bakteriologische Zwecke) E Liebreich

64 **Puerperal Fever**—Jung concludes his long study of puerperal infection by emphasizing the paramount importance of the nursing of patients, care to ward off bed-sores, and nourishment at frequent intervals, possibly every hour, giving some nourishment even through the night The heart must be constantly supervised The puerperal fever may run a rapidly fatal course, but sometimes it drags along for weeks and months, the family alternately in hope and despair, and constantly urging the physician to "do something more," give intra-uterine douches, collargol intravenously, etc In yielding to these lay demands we must guard against doing harm By giving the intra-uterine douches ourselves, we can restrict them to the vagina and leave the uterus to its indispensable repose If the patient happens to improve after any remedial measures, Jung begs us to be critical enough to distinguish between *post hoc* and *propter hoc* and not to rush into print with the case

The tendency to remove the uterus in every severe case is less evident now than some years ago as we have no means for determining which are the really desperate cases until too late for hysterectomy to do any good The same objection applies to ligation of the pelvic veins Any chill may be the last one and recovery ensue, with or without the ligation The operation in itself has a high mortality, but it might be ventured in chronic cases with many chills but comparatively good resisting powers He adds that gonorrhea may induce a syndrome resembling the classic puerperal fever When preexisting gonorrhea is known the diagnosis is easy, but otherwise it is seldom thought of Women known to have gonorrhea should be kept in bed longer and special care be taken to avoid stagnation of lochia Ergot and the ice bag are especially useful here Bacteriologic examination of the secretions is the only means to positively differentiate gonorrhea This is important for various reasons, not the least of which is the exoneration of the physician or midwife for responsibility for the puerperal fever Gonorrheal puerperal fever almost invariably terminates in recovery, although it usually entails local changes The local gonorrheal affections require only conservative measures during their acute phase The woman is generally left incapable of further childbearing He warns further that the virus of tetanus is extremely hard to get out of a room that has once been infested with it Puerperal tetanus is almost inevitably fatal When typhoid is epidemic, it might be advisable to vaccinate the parturient against it

71 **The Tubercle Bacilli Not Mobilized by Tuberculin**—Mollers and Oehler report that examination of the blood of fifty-four tuberculous patients before and after injection of tuberculin failed to show any evidence that the tubercle bacilli are mobilized and driven into the blood by the injected tuberculin

75 **Acute Infectious Jaundice**—Trembur and Schallert remark that the recent discovery of the spirochete causing Weil's disease was made on the group of cases they here report in detail, eleven in all, scattered through five months The illness came on suddenly, with headache, sacral pains and leaden fatigue in the limbs, soon changing to pains, especially in the calf muscles and thighs The pains were sometimes so severe that the men cried out, and the muscles were unbearably tender to the lightest touch The jaundice did not develop until from three to seven days after the onset of symptoms Vomiting, nose-bleed, mucous diarrhea followed by constipation, swelling and redness of the conjunctiva and throat, vertigo and pains in swallowing were other features of some of the cases An initial chill was noted in three cases, in the others there was merely a sensation of chilliness before the fever came on The fever charts show one or more relapses of the fever in some cases, bronchitis was evident in all Necropsy revealed pneumonia in the one fatal case, and hemorrhagic erosions and follicular ulceration in the mucosa of the large intestine from the rectum to the ileocecal valve The liver was enlarged in all but three and the area of heart dulness was enlarged, the pulse small, rapid and irregular An operation for gallstones was done in one of the earlier cases, but none were found and the diagnosis was then corrected to Weil's disease In treatment, stress was laid on food that promoted coagulation of the blood, red wine gelatin and meat juice jelly Convalescence was slow Air cushions were used to prevent bed-sores, the position was frequently changed and the men were urged to "breathe deep" Diuresis was promoted by subcutaneous injection of 0 85 per cent salt solution

78 **Edema of the Kidney**—Meyer applies this term to serous infiltration of the kidneys themselves The kidneys of persons who have died from chronic parenchymatous nephritis are often enlarged and abnormally heavy from this serous infiltration, and he thinks that this is responsible for more of the various symptoms than is generally recognized In a typical case of renal dropsy in a young woman who had long refrained from salt in her food, he scarified the legs and in forty-eight hours 11,700 c c of edema fluid thus drained away and by the fourth day she had lost in this way 14 liters of fluid Diuresis improved at once and the general condition After five days of improvement the condition grew worse again, the urine output declined to 500 c c and the anasarca increased again On repeating the scarifications, the condition improved remarkably anew and has persisted good during the year since Except for occasional slight swelling of the ankles and legs the aspect is normal, the urine output keeps between 1,600 and 1,800 c c, the specific

gravity about 1 010, the albumin content between 5 and 8 1,000 The blood pressure and fundus of the eyes have shown no pathologic changes The case is cited as confirming the assumption that the kidneys were suffering from serous infiltration, as well as the other tissues and organs The edema included the kidneys, and the functioning of the kidneys had suffered in consequence The condition was similar to that with stasis in the kidneys which can be relieved by venesection or decapsulation The benefit from the latter is probably due to the same mechanism, relieving the tension from the edema of the organ When diuresis sets in after decapsulation and the kidney functioning improves miraculously, as many have reported, Meyer thinks that the same result might probably have been attained by breaking up the vicious circle at some other point Scarification seems to be the simplest and most harmless of all means for this purpose At least, he insists, it should be given a trial before resorting to an operation

79 **Behavior of the Leukocytes as Guide in Tuberculin Treatment.**—Brosamlen has found the changes in the morphologic blood picture useful as biologic criteria for the effects of tuberculin treatment He examined the blood three times a day after the daily injection of tuberculin There was always more or less leukocytosis, most marked and most durable when the temperature reaction was most pronounced The neutrophils and the eosinophils showed the greatest proportional increase Those patients who bore the tuberculin well and showed improvement under it, both subjective and objective, always reacted to the injection with an increase in the eosinophils There was no increase when the therapeutic effect of the injection was interfered with by an intercurrent affection or other cause It proved possible by this regular examination of the blood to foretell—from the absence of any increase in the eosinophils—when an intercurrent affection or the like was impending, and, by reducing the dosage or lengthening the intervals, be prepared to meet it. Those patients who showed no increase of eosinophils or a decline did not thrive under the tuberculin treatment It seems probable that the eosinophilia may be regarded as an index of the development of certain protective forces Cases in which these do not develop—as indicated by the absence of an increase in the numbers of eosinophils—he regards as unsuited for tuberculin treatment, other things being equal

82 **Treatment of Vulvar Pruritus**—Edenhuizen is convinced that most cases of vulvar pruritus are due to irritation from the secretions Hence she combats it by careful cleansing, painting with tincture of iodin, and keeping all moisture away from the region All cleansing of the anus and vulva is done with cotton wads dipped in oil Exercise is restricted to avoid perspiration, and the vagina and entire genital region are kept powdered dry, three times a day Tampons in the vagina collect the discharge during menstruation With this combined treatment kept up for six or eight weeks, the irritation subsides completely and the pruritus is permanently cured after possibly years of torment The details of six typical cases are given She warns that the iodin may smart for an hour or so, in two cases she had to inject a sedative on this account. In these cases there was eczema in the vulvar region The iodin and powder applications were repeated every third and later every fifth day when there was eczema Zinc oxid was the powder used mostly The cure, she reiterates, depends on keeping all moisture away from the region After urination and defecation the meatus and anus are wiped with oiled cotton, then with dry cotton and then powdered

93 *Tuberculosis in War (Tubercolosi in guerra) A Fagiuoli

April 9 No 29 pp 449-464

94 Examination of Infants Stools as Aid in Diagnosis (L'esame delle feci nelle malattie gastrointestinali del lattante) G Funaioli

93 **Tuberculosis and War**—Fagiuoli in commenting on the numbers of soldiers found to be tuberculous, says that the hardships and vicissitudes of the campaign are ample to explain the rousing of latent tuberculous processes to an active destructive course, but that probably direct recent contagion is responsible for a certain proportion of the morbidity On the other hand, he knows of instances where the camp life seems to have given the finishing touch to the cure started under sanatorium or dispensary treatment, and the men are now found rugged and free from any signs of tuberculosis He urges that every province should make arrangement for one or more sanatoriums for tuberculous soldiers and that measures should be taken to make the soldiers take the needed courses of sanatorium treatment The soldier has but one wish, he says, and that is to return to his family, and the sick long for this even more than others So it will be a difficult matter to get them to take proper sanatorium treatment The military authorities may have to refuse to discharge the man from the army after the war until he has taken the required course of treatment The sanatorium physician should be empowered to keep the man three or six months as his condition requires

108 **Pathogenesis of Epitheliomas**—This communication reports the results of research financed by the Japanese Cancer Research Society It is profusely illustrated with twenty plates which show the successful outcome in 61 5 per cent of the experiments It was found possible to induce the production of an epithelioma at will on the ears of rabbits painted systematically with tar This occurred on thirty-two of the fifty-two ears thus treated for several months In three cases the epithelioma showed the typical infiltrating growth of carcinoma, but there was no tendency to metastasis apparent in any case, and attempts at transplantation never gave positive results The experiments related are said to confirm Yamagiwa's statement that no superposed specific irritation is necessary for carcinoma to develop, all that is necessary is to continue the irritation that has brought the soil into the precancer stage The experiments further confirmed the importance of age in development of cancer The increased keratosis under the influence of the tar applications may be regarded as an artificial senility of the skin in the region painted

110 **Action of Epinephrin on Secretion of Sweat**—Muto's sixteen mostly two-page charts show the increase in sweat production when epinephrin, atropin, chloral or pilocarpin was injected intravenously or subcutaneously into twenty horses, four sheep, three calves and two cats Photographs are also given showing the pools of sweat under one of the horses under the influence of epinephrin, and the pool of saliva under pilocarpin He collected the sweat with a large funnel-shaped leather bag extending under the entire body and neck of the horse The total amount of sweat from one horse under the epinephrin was 1,230 c c The research was undertaken to ascertain whether or not the sweat glands are innervated by the sympathetic system exclusively The findings indicate that both the sympathetic and the parasympathetic systems are involved The latter predominates in man, cats and cattle, while the former is chiefly involved in the horse and sheep

115 The Mode of Action of Vasoconstrictors and Vasodilators With Internal Hemorrhage G A Lubenetzky

114 **Suture of Vessels**—Novikoff found in Carrel's method of suturing injured vessels an ideal physiologic procedure which deserves widespread use, even in the absence of suitable instruments and silk Suturing of even small vessels gives excellent results if the edges of the torn vessels are freshened and cut obliquely, or in any other way to prevent narrowing of the lumen Traction on the ends of the vessel must be avoided Suppuration does not prevent vessel suturing, but Esmarch's band must be ready for use in order to prevent a possible secondary hemorrhage He gives histories of 8 cases with complete success in 5 In 2 the suture yielded, and secondary hemorrhage occurred on the seventh day in one case after the operation, which necessitated ligation of the vessel One patient died the day following the operation because of severe loss of blood before and during the operation In the other 5 cases smooth recovery followed

Hospitalstidende, Copenhagen

March 29, LIX, No 13, pp 273 303

116 *Low Gravity Abscess From Tuberculous Process in Sacrum (Pyriformis Abscessen) T Rovsing
117 *Dyspepsia With Chronic Alcoholism F Vogelius and G Wiltrup Commenced in No 11

116 **Pyriform Abscesses**—Rovsing applies this term to the puzzling abscesses and fistulas above and near the hip joint which return with exasperating persistence again and again after being curetted and apparently healed He had about given up the hope of ever curing cases of this kind, when the introduction of bismuth paste as a diagnostic measure cleared up the puzzling syndrome at once It showed that the low abscess was merely the lower part of an hour-glass abscess, the upper and primary process being in the inner surface of the sacrum The pus sinks down along the pyriformis muscle and emerges with this muscle through the greater foramen It collects below where it is usually mistaken for a primary process in the trochanter or hip joint or for bursitis He reports four cases with a typical recurring course for eleven, eighteen and twenty years before the bismuth paste revealed the true nature of the trouble. It was an easy matter then to cure it permanently by curetting and providing ample drainage This cannot be realized with a parasacral incision, so he incised on the median line and resected the coccyx The focus was then reached by working subperiosteally from the lower margin of the sacrum The focus was thoroughly scraped out and the fistula below flushed with 6 per cent aqueous solution of phenol The pelvic fascia were left undisturbed and a stout-walled drain was introduced into the focus, the lower end brought out through the incision below The skin was sutured around it with aluminum-bronze wire He says that Beck's book on the use of bismuth paste gives illustrations of two typical cases of this pyriformis abscess Rovsing does not agree with Beck, however, that bismuth paste is an effectual therapeutic measure, on the contrary, as it plugs the fistula, the secretions accumulate above and dire damage may result. With the above described operative measures his four patients were entirely cured in about seven weeks

THE NONSPECIFIC FACTORS IN THE TREATMENT OF DISEASE [*]

JAMES W JOBLING, M D
AND
WILLIAM PETERSEN, M D
NASHVILLE, TENN

As a natural consequence of the phenomenal advances of the past thirty or forty years in our understanding of disease processes and in what may be termed therapeusis by means of biologic products — advances largely the result of laboratory and more especially immunologic research — medical consciousness, if we may so regard the literature, has rather wholly centered about ideas of specificity, and, taking its cue from the laboratory, has regarded with considerable skepticism and frank disapproval any reference to observations, especially if clinical, at variance with the current trend of thought And yet one finds a not inconsiderable accumulation of evidence, both from the laboratory and from the clinic, forming in a measure an undercurrent, definitely indicating a much larger share of certain nonspecific and as yet ill defined factors in recovery from disease While the emphasis placed on certain phases of immunology and specificity, more especially the fruitful antigen-antibody conception of Ehrlich, has been of inestimable value, we rather believe that it has resulted in the neglect of certain perfectly obvious lines of approach to medical problems

Quite early in the development of the tuberculin therapy it will be recalled that Matthes[1] demonstrated conclusively that to all intents and purposes the reaction considered specific for tuberculin could be produced when deutero-albumose was used, and showed that whatever difference occurred could be explained by the fact that the tuberculin fraction contained certain toxic peptones in addition Matthes went even farther, expressing the idea that fever in general was produced by protein split products and suggested the importance of proteolytic ferments in this connection, thus foreshadowing the work of Vaughan in this country and the later German workers in anaphylaxis

The history of the treatment of typhoid fever with vaccines is quite similar Fraenkel many years ago demonstrated, in a convincing series of cases, the therapeutic value of typhoid vaccine used subcutaneously Directly Rumpf followed him with a series of cases treated with a vaccine of *Bacillus pyocyaneus* with equally favorable results But since the medical profession could see no merit in a nonspecific method, the entire subject was dropped for a considerable period of time In this country, too, the controversy occasioned by the Schafer vaccine is pertinent Here was a biologic product, which, according to the observation of many competent observers, did at times produce striking results in a variety of infectious diseases, whether or not it was a safe remedial measure, and whatever may have been the defects, is not pertinent in this connection The very fact that it did do certain things at times should have led to a study of why such favorable changes were brought about The fact that it was palpably nonspecific, however, was sufficient to warrant the stamp of disapproval by the medical profession

It is only within the last two years that a certain definite movement away from this rather narrow point of view has occurred, and it is significant to note that Wright,[2] than whom, of course, no one man has stood out more emphatically for specific therapy, recently made the following statement in this connection

> All those who have had much experience with vaccines will have seen cases where therapeutic effects, lying quite outside the range of the particular vaccine employed, *and therefore, as we thought, not quite creditable to science,* have been obtained by vaccine therapy

Schmidt[3] is among those who have called attention to the fact that following vaccine therapy of any kind the body becomes resistant to a variety of the commoner infections So too, it seems that during carcinoma and pregnancy (both, by the way, conditions distinguished by their high antiferment titer) a relatively low "infection index," as Schmidt terms it, is established

Von Wagner utilized a similar nonspecific method when he obtained favorable results in paretics treated with tuberculin, and only recently Blach[4] has reported a series of cases of early syphilis treated with tuberculin

We cite these not to recommend the treatment, because it hardly seems warranted, possessing as we do much more efficient agents, but to indicate the same general phenomenon of a therapeutic effect from a nonspecific method

It is in the domain of coagulation disturbances that therapy of this nature has received particular attention in the past The beneficial effect of subcutaneous serum injections in hemophilia is well recognized, although here too the exact mechanism is unknown Originally the slight leukocytosis was regarded as the potent factor, but for this there is no warrant Results have been obtained with homologous and heterologous serum, and with whole blood, but decisive results depend considerably on the dosage, and marked fluctuations in coagulation time frequently occur following such injections That such injections do not alter the disease process through supplying directly some deficiency, but rather through stimulating the elaboration of some substance before lacking, would seem to be the conclusion reached by recent workers This would agree with the stimulating effects observed from injecting serum and whole blood subcutaneously in tuberculosis and pernicious anemia (Esch, Busse, Weber)

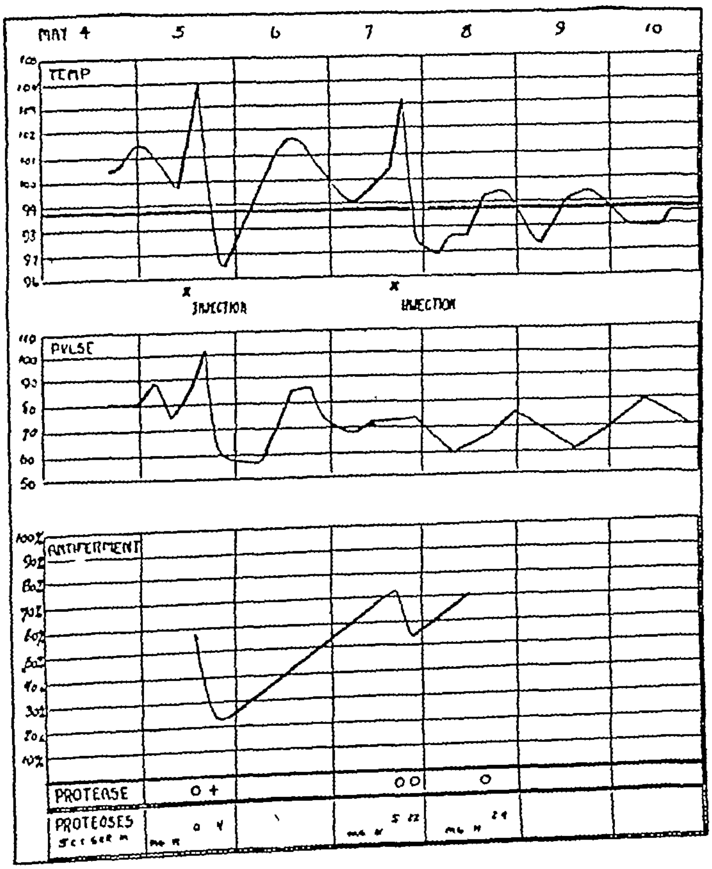
The dermatologists have within the past two years had similar results in a variety of diseases, including some cases of psoriasis which had proved refractory to other methods of treatment As a rule the homologous serum was injected intravenously in these cases

The therapy of typhoid fever has so far been the chief avenue of approach to the problem A number of vaccines have been elaborated and used subcutaneously during recent years for therapeutic purposes, and the results have been, in general, very encouraging It was not, however, until such vaccines were used intravenously that the striking pictures of complete abortion of the disease were obtained Then Kraus[5] observed that colon vaccines gave an identical result, while the typhoid vaccine was of marked benefit in certain cases of pelvic infection Ichikawa[6] found that his paratyphoid patients recovered with a typhoid vaccine, while Ludke[7] went a step farther, using a nonbacterial protein split product—a deuteroalbumose — with equally favorable results, in typhoid fever The effect of such an injection of secondary proteoses in typhoid fever is shown in the accompanying chart



Intravenous injection of secondary proteoses in typhoid fever J S (City Hospital, courtesy of Dr McCabe) Illness commenced April 29, one week before admission to hospital, Widal positive on admission, 1 5 c c proteoses injected intravenously May 5 (2 per cent solution), 2 c c proteoses injected intravenously May 7 (4 per cent solution) Protease became positive after first injection Lipase titer increased from 0 6 c c hundredth normal sodium hydroxid, May 5, to 1 9 c c hundredth normal sodium hydroxid per cubic centimeter of serum, May 8 Proteoses in the serum increased from 0 1 mg (nitrogen) per 5 c.c. serum to 0 24 mg, May 8

Apart from the action of the vaccines, the protein split products, and the effect of both homologous and heterologous serums, observations are recorded of the effect of milk injected intramuscularly (Schmidt), salt solution (Mitlander), dextrose solution, colloidal metals, distilled water (animal experiments) and ferments (including the leukocytic extract of Hiss and Zinsser) It seems probable that the reaction and beneficial effects observed from these substances is based on a similar mechanism in all cases

SELECTIVE STIMULATION

Latterly the hematopoietic organs have come to be recognized as the chief source of antibodies, a recent paper by Becht and Leuckhart[8] demonstrating in a convincing way that the circulating antibodies are not derived from the tissue cells in general, an origin that would presuppose the discharge of these substances into the general circulation by way of the lymph stream As a corollary of this idea concerning the source of the antibodies, it would seem reasonable to suppose that any disturbance of the hematopoietic system might alter the antibody formation, an observation of Moreschi[9] quite bears this out Moreschi noted the persistent absence of agglutinins in leukemic patients suffering from a superimposed typhoid infection

In view of these facts, it would seem possible that the various agents act as stimulants of the hematopoietic tissue, which, as a consequence, suddenly floods the body with antibodies, thereby overcoming the infection According to the idea of Wright, vaccine injections were supposed to be followed by a negative phase, at least as far as the opsonic power was concerned Contrary to this generally accepted view, Bull[10] has recently shown that this does not hold true following the intravenous injection of a typhoid vaccine in immunized rabbits Bull noticed that the antibodies were not diminished, on the contrary, they were rapidly increased following the injection If this is the mechanism involved, it is important to keep in mind that the stimulus itself is not a specific factor, but that the hematopoietic system has been attuned to respond to a nonspecific stimulus with the production of specific substances Dunklin, working in this laboratory, finds that a marked increase in antibodies follows the intravenous injection of proteoses in immunized rabbits In a general way this mechanism of recovery would consist of a selective stimulation of the hematopoietic system by nonspecific substances

THE LEUKOCYTOSIS

The importance of the leukocytic reaction has been emphasized by Gay and his associates They believe that the recovery following such intravenous therapy (they worked with a modified typhoid vaccine) is due to a specific hyperleukocytosis More recently, however, McWilliams[11] has observed that this hyperleukocytosis is apparently not specific to the degree indicated by the work of Gay and Claypole,[12] and that even normal rabbits respond with a marked leukocytosis to the intravenous injection of typhoid vaccine This coincides with our own experience We must keep in mind, too, the fact that in typhoid fever particularly, the normal course of recovery is not marked by a leukocytosis, on this ground alone we might be justified in seeking the influence of some other factor or factors in the recovery following intravenous therapy

THE HYPERPYREXIA

It is a common clinical experience that in some diseases, among them subacute joint diseases, neuralgia, diabetes, pernicious anemia, certain dermatoses, sarcoma, etc, distinct beneficial results follow at times on some intercurrent febrile condition Is it possible, therefore, that these varied agents influence the course of the disease by producing a high temperature?

A long list of investigators, among them Walther, Hildebrand, Englehardt, Rolly and Meltzer, have reached the conclusion that a high temperature (from 40 to 42 C or 104 to 107 6 F), artificially produced, has a favorable influence on an established infection Lower temperatures, on the other hand, as recently noted by Winslow and his associates,[13] would seem to retard the formation of immune bodies Inasmuch as a very sharp febrile reaction almost invariably follows the intravenous injections, the importance of this phase of the subject cannot be overlooked In our own cases we have at several times observed a reaction temperature of 107 F within one-half hour following a proteose injection (in typhoid patients) , unaccompanied by a change of the pulse rate of any moment or other untoward symptoms

THE MOBILIZATION OF FERMENTS

We have already[14] pointed out that in experimental animals the intravenous injection of bacteria, kaolin, protein split products and trypsin is almost invariably followed by more or less marked mobilization of serum protease and usually of lipase (esterase)

In the patient a similar reaction occurs following the intravenous injection of vaccines and proteoses, but not to the same degree nor with the same regularity as in animals In considering the possible effects of such a mobilization of ferments, both protease and lipase, we must keep in mind that a variety of reactions may occur The serum protease, as other tryptic ferments, is without effect on bacteria, but if we consider the source of the intoxication occurring in the diseased organism as primarily due to protein split products, then such a mobilization of protease may be of considerable importance in the process of detoxication, in that the toxic fragments are hydrolized to lower and nontoxic forms We have discussed this possibility in detail in its relation to pneumonia [15]

As a result of this effect the diseased organism would rid itself for the time being of the toxic substances circulating at the time of the injection, although the disease process itself, and the infecting organisms, would possibly continue in existence capable of further injury This would seem to be the explanation for the clinical picture obtained after intravenous therapy in such instances in which only an incomplete or transitory effect results In all these cases the patients present a considerable improvement, both subjectively and objectively, on the day or days following the injection, despite the fact that the temperature may recur or even continue uninterruptedly

The influence of the fat-splitting ferments mobilized is as yet obscure In the ultimate analysis, of course, we must turn to ferments of this nature for the attack on the invading organism, because it is more than probable that the actual surface of the bacterium consists largely of lipoids, or intimate lipoprotein combinations, for the destruction of which fat-splitting ferments are essential In certain infections with lipoid-rich organisms, such as tubercle and lepra bacilli, the clinical demonstration of the association of a high lipase titer in the serum, with a favorable prognosis, has been well established At present, however, the subject is still one in which only diligent inquiry will furnish definite knowledge

THE INCREASE IN ANTIFERMENT

When discussing the low "infection index" observed during the course of certain conditions, among them carcinoma, pregnancy and following vaccine therapy (Wright emphasized the latter finding particularly in his report on the antipneumococcus vaccination at the Premier Mine), we called attention to the fact that during such states a relatively high antiferment index is a well recognized accompaniment The question arises whether this is a mere coincidence or whether there is some causal connection between the antiferment increase and the increased resistance to infection

We have previously shown that the antiferment power of the serum depends on the amount of unsaturated lipoids present in a highly dispersed state in the serum [16] Consequently, any factor that will tend to increase these lipoids, be it by increasing the supply or by decreasing the utilization (as when the lipase in the serum is decreased) by injuring tissue cells and causing them to discharge such lipoids to the blood stream, will increase the antiferment titer, while conversely, any influence decreasing these lipoids, their dispersion or their unsaturation, will tend to decrease the titer

It is particularly the state of dispersion of these lipoids that is ignored by most investigators of their physiologic properties Serum lipoids in coarse dispersion are inactive as antiferments as well as in the mechanism of coagulation, a fact that should be kept in mind when the effects of lipemia are considered

Wright worked with saprophytic and serosaprophytic organisms, and noted that the addition of antiferment to the culture medium completely checked the growth of the serosaprophytic bacteria, and found that even the saprophytic bacteria grew less luxuriantly when no trypsin was added In view of the results obtained by Rettger, Berman and Sturges,[17] showing that the ordinary infectious organisms are not able to derive their protein requirement from native or even partly hydrolized proteins, but probably solely from the lowest degradation products, the direct influence of the antiferment cannot be so simple as Wright would assume The antiferment inhibits only the action of the tryptic and not the peptolytic and ereptic ferments Of course, when we are dealing with a definite tryptogenic organism it becomes apparent that an increase in antiferment would offer an increased factor or resistance against its growth

[16] Jobling J W and Petersen William Jour Exper Med 1914 xix 459

[17] Rettger L. F Berman N and Sturges W S Jour Bacteriol 1916 i 15

An increase in the serum lipoids affects bacterial growth, however, in another way, since an adsorption of lipoids occurs at the surface of the bacteria The relation of this adsorption, seemingly a nonspecific and purely physical process, to the phenomenon of sensitization, is as yet not clear It is reasonable to suppose, however, that the metabolic exchange of the bacterial limiting membrane is markedly influenced by increased lipoidal adsorption on the surface, resulting not only in influencing the metabolism unfavorably, but possibly preventing the excretions of substances protective for the bacterium (leukocidins, virulins, etc)

The immediate effect of the vaccine and proteose injections is not an increase, but a distinct decrease in the antiferment titer for a short period of time, followed later by a rise It is probable that the decrease is due to the chill which occurs after the injections, the increased metabolic demands of the organism being met in part by the rapid utilization of the serum lipoids

CONCLUSION

It seems probable that the fundamental change on which the majority of the above described biologic reactions are based is one of colloidal dispersion, in that the injections bring about a less dispersed state affecting not only the serum proteins but also the serum lipoids Such an alteration is sufficient to account for the fluctuations in the ferment-antiferment balance, and in the coagulation mechanism, as well as in the opsonic and complement powers of the serum, although it does not at present explain the increased antibody titer With this as a basis we can understand that so many and diverse substances can bring about a reaction almost identical clinically and therapeutically But here, as in so many other biologic problems which have to do with that most complex of tissues, the blood, it seems probable that no single factor can be identified as responsible for all the changes which occur, but that a whole train of events is inaugurated when the equilibrium of some of the delicate serum balances is disturbed, all of which tend toward a condition favorable for recovery from infection

---

THE TREATMENT OF ARTHRITIS BY THE INTRAVENOUS INJECTION OF FOREIGN PROTEIN *

JOSEPH L MILLER, M D
AND
FRANK B LUSK, M D.
CHICAGO

During the past year attention has been called to the value of intravenous typhoid vaccine in the treatment of typhoid fever The early reports by Penna, Kraus and Mazza of Buenos Ayres, and the independent investigation by Ichikawa, demonstrated clearly that by this method of treatment a certain percentage of typhoids might be brought to an immediate termination Kraus and somewhat later Ludke were able to show that similar results could be obtained with a vaccine made from colon bacilli, this showing definitely that the reaction was not due to a specific vaccine Ludke later was able to show that a solution of albumose would accomplish the same results[1]

During the past summer we used the intravenous typhoid vaccine, 200,000,000, in the treatment of typhoid Later, following the suggestion of Ludke, we thought it might be of interest to compare these results with a series treated with albumose We were unable to obtain any of Merck's albumose, but through the courtesy of Drs Jobling and Petersen of Vanderbilt University we secured some proteose which they had prepared for their experimental work By giving from 1 to 2 c c of a 4 per cent solution of this proteose, we obtained the same results as with the typhoid vaccine, 20 per cent of the treated cases terminating by crisis after a single injection In addition, in about an equal number following the injection there was a termination by rapid lysis, and in a third group, which again equaled approximately 20 per cent, following a single injection, the continuous fever was changed to a very irregular type, which continued until the termination of the disease The remaining cases, while reacting with a chill and rise in temperature, continued their febrile course in an uninterrupted manner As stated, the proteose, in its chill, temperature reaction, leukocytosis and percentage of cases in which the course of the disease was modified, gave the same results as the typhoid vaccine

These results are simply confirmatory of those already recorded, making it quite apparent that the sudden termination of the disease is not due to the specific character of the vaccine, but probably to the action of a foreign protein It was decided to apply this method of treatment to another infection, and we selected for this purpose acute, subacute and chronic arthritis In the selection of our material, the patient after entering the hospital was kept in bed for two or three days without special medication for observation as to how much improvement might follow simple rest It was quite surprising to see how many patients with acute arthritis, after two or three days' rest in bed, were so much improved that we did not consider them suitable subjects for testing out the value of a therapeutic agent Selecting, then, only those cases for study in which the disease was of a persistent type, we gave a 4 per cent proteose solution, in doses of 2 c c, intravenously The patient reacted by a chill, rise in temperature and moderate leukocytosis The day following the injection there was a moderate but definite improvement in the joint symptoms

As our supply of proteose was limited, and as we believed that the reaction was due solely to the foreign protein, a typhoid vaccine was substituted for the proteose This vaccine was prepared from the Rawling's strain, killed by heating to 55 C and preserved by 0 5 per cent phenol (carbolic acid) In the preliminary cases a dosage of 150,000,000 was given intravenously The reaction was the same as when the vaccine was given to a typhoid patient except that the leukocytosis was much more marked, in two instances reaching 52,000 Immediately following the injection there was a moderate leukocytosis which increased slightly until the chill, which usually occurred in from five minutes to one hour During, or immediately following the chill, there was a rapid drop in the leukocytic curve, resulting either in a normal count or a leukopenia, followed promptly by a rapidly developing leukocytosis which reached its maximum usually at the end of four and occasionally at the end of twelve hours, gradually returning to normal in from twenty-four to forty-eight hours

---

* From the Medical Clinic of Cook County Hospital

[1] For complete references to the literature the reader is referred to the paper by Frederick Gay, Journal of Laboratory and Clinical Medicine, 1915, 1, 13

The degree of leukocytosis was dependent in a measure on the acuteness of the infection Twice in acute arthritis the leukocyte count reached 52,000, while with the subacute forms it rarely passed 25,000 Following the chill there was a profuse sweat which continued for several hours, in three patients a second chill, with slight leukocytosis, from six to seven hours after the injection was recorded When a patient received daily injections there was a gradual lessening in the duration of the chill, and finally the patient failed to react with a chill As an illustration, following the first injection the chill lasted one hour, after the second thirty-five minutes, after the third fifteen minutes, and after the fifth injection rigors did not occur The maximum temperature was reached, not at the time of the chill, but three to five hours after the injection In several instances a leukocytosis occurred without chill, but in none of these was there improvement in the patient's condition In acute arthritis a temperature of 105 was not unusual Subacute arthritis gave a milder reaction When the vaccine was repeated daily with each successive dose the degree of febrile reaction grew progressively less To illustrate, in one case the temperature after the first injection reached 105, after the second 103 4 and after the third 102 Nausea and headache were noted practically constantly after early injections, the headache continuing at times for twenty-four hours The pulse rate during the height of the fever never exceeded 120, and in no instance was there evidence of collapse or serious consequences

Later the dosage was reduced to 75,000,000 With this amount the reactions were possibly slightly less violent, whereas with the proteose the results were definite but not striking, with the typhoid vaccine they were quite as remarkable, as is noted in typhoid patients treated in the same manner and according to our experience much more constant In three of our ten cases of acute articular rheumatism, immediately following a single intravenous injection of 150,000,000, the fever terminated by crisis, the joint tenderness began to disappear, and within from twelve to twenty-four hours the joints were apparently normal In these three cases the results were permanent All of the seven remaining patients were very much benefited following a single injection, but the results were either not permanent, or soreness still remained in some of the affected joints Three or four injections, however, sufficed to relieve all symptoms Some of these patients after treatment remained in the hospital a week or more apparently well After discharge, mild recurrences took place and the patient returned for further treatment We wish to emphasize that in all this series, great relief followed one, or at most two treatments, relapses, however, were frequent Five weeks have now elapsed since some of these patients were discharged, and no relapse has occurred We are, therefore, justified in saying that recovery in some cases following even a single injection is permanent We are now giving all our patients, even if the symptoms all disappear after a single injection, daily injections until four or five have been taken in order to see if relapses can be avoided

Results quite as satisfactory were obtained in six cases of subacute arthritis of from three to nine months' duration These patients all received several injections Here, as in the acute cases, great relief followed a single injection, and after three or four injections had been given, the patient could move his joints with comfort, could dispense with his cane, and in every way the results were most gratifying It is scarcely to be expected if these cases are due to a chronic focus of infection that the results will be permanent We are keeping in touch with these patients, and up to the present time (four weeks) no evidence of marked recurrence has been noted One patient with chronic arthritis of three years' duration received considerable relief after five injections

Results even more striking were noted in cases of chronic gonorrheal arthritis of from two months' to three years' duration One of these patients, who had a wrist involvement of three months' duration with complete disability, recovered apparently completely within forty-eight hours after a single injection, with free movement of the affected joint, and now after a lapse of four weeks there has not been any recurrence The seven other patients in this series all received decided benefit following a single injection, and after repeated treatments (one having received thirteen) the results have been such as to encourage further use of the vaccine None of these patients failed to receive decided benefit On the other hand, two patients with acute gonorrheal arthritis were only moderately benefited

The nature of the reaction effecting these changes, it is difficult to explain That the same process is active here that is responsible for the termination by crisis in typhoid, following intravenous vaccine, is highly probable That the reaction here and also in typhoid is a foreign protein, and not a specific protein, is probable Vaughan has shown that animals immunized to *Bacillus prodigiosus* and *B subtilis* also have a certain degree of immunity to typhoid and cholera He was also able to obtain the same degree of transitory immunity to colon bacilli in animals, by the use of egg albumin, as he had been able to obtain with the products of the colon bacillus In our cases of arthritis, while the joint manifestations might permanently disappear after one or more injections, in case the patient had an endocarditis or pericarditis this would run its usual course (and it was these patients who showed a marked tendency to relapse), or in case of gonorrheal arthritis following the injection the discharge would be temporarily increased rather than diminished This localized immunization recalls to mind Faber's work on joint sensitization in arthritis, and suggests the question whether as a result of the vaccines it was possible the joints might become desensitized That the febrile reaction following injection is not due solely to the foreign protein injected is suggested by the much milder reactions in patients with low degrees of infection Jobling and Petersen suggest that for this reason part of the reaction is probably due to the foreign protein in the bodies of the destroyed bacteria exciting the infection, the destruction being due to mobilization of antibodies While our results with proteose were slight, they were nevertheless definite When the splitting of the protein can be properly adjusted, it is highly probable results similar to those following the typhoid vaccine may be obtained, with possible elimination of that portion of the reaction arising from the injected material

Whether or not further experience will show that this method of treatment is of value as a therapeutic agent, it will at least give further evidence of the nonspecificity of vaccines It does not, however, involve the specificity of vaccines for preventive purposes

THE VALUE OF ANAPHYLAXIS IN THE TREATMENT OF GONORRHEAL COMPLICATIONS

ALLERGY, A THERAPEUTIC AGENT?*

LOUIS D SMITH, M D
CHICAGO

Serum therapy in infectious diseases has earned a justly prominent place Passive immunization in diphtheria and tetanus is an established fact Excellent results have been obtained with this form of immunization in epidemic meningitis, although the *Diplococcus intracellularis-meningitidis* elaborates no ectotoxin Less certain immunization therapy, in the nature of bactericidal, bacteriolytic or agglutinative serums, has been accomplished in streptococcic bacteremia, Asiatic cholera, bacillary dysentery, pneumonia and other infectious diseases In gonorrheal complications, such as rheumatism, beneficial results have been obtained with antigonococcic serum, and the assumption is that with the administration of the serum there has been the introduction of specific antibodies

Serum therapy is not limited in its field of usefulness to specific immunity Diphtheria antitoxin has been employed successfully by Noel Paton[1] in various septic conditions He further found the same good results when employing normal horse serum in tuberculosis, arthritis deformans and cerebrospinal meningitis Normal human serum has found a most favorable field in scarlet fever and even in systemic and nervous syphilis Further, Herescu and Strominger,[2] in the exploitation of the meningococcus on grounds of morphologic relationship with the gonococcus, investigated antimeningococcus serum in its effect on gonorrheal complications, with the discovery that most excellent results were obtained in arthritis, ophthalmia, septicemia, ureteropyelitis and meningitis of gonorrheal origin One must be struck by these bizarre findings, and the temptation presents itself to investigate the cause While working with antigonococcic serum in the treatment of gonorrheal complications, my attention was attracted to the fact that the individuals who were markedly affected by anaphylaxis were the ones who responded to the treatment with the serum Furthermore, the severer the manifestations, such as temperature, urticaria, joint pains, etc, the better the result Again, no marked effect was noticeable until these anaphylactic manifestations appeared Lastly, in the absence of the allergic symptoms no effect on the disease, subjectively or objectively, was obtained

This seemed more than a coincidence, and in reverting back to my older records of all such cases, it was evident that the same conditions had obtained in the majority of the cases so treated The following two cases typify what is meant

CASE 1—E B, a printer, aged 22, had had gonorrhea for nine weeks when he developed right-side epididymitis, with all the subjective and objective signs and symptoms typical of that complaint The first, second and third glasses of urine were turbid He was immediately given 15 c c antigonococcic serum intramuscularly, followed by 24 c c the next day There was no change in his condition until six days after the last injection, when he developed a temperature of 101 6, had a generalized urticaria and felt very sick He appeared for examination the second day of his illness with all the soreness in the scrotum gone, the swelling markedly reduced, and the second glass of the two-glass test perfectly clear In two weeks he was completely cured with routine treatment

CASE 2—G A, had had gonorrhea for seven weeks, and presented the usual signs and symptoms of a posterior urethritis He developed a left-side epididymitis three days after coming under my observation, and was immediately given 36 c c antigonococcic serum extending over a period of four days Two days following the last injection, he was taken alarmingly ill with a temperature of 104 dyspnea, general malaise, joint aches, and a violent urticarial eruption These symptoms subsided after the third day, when he reappeared for examination I was astonished to find a complete recovery from the infection, including even the anterior urethritis, all facts having been verified by continued observation for a period of six months

The following case is even more striking in that it gives unimpeachable evidence of the dependency of the beneficial results on the appearance of serum sickness

CASE 3—A R, a salesman, developed epididymitis twelve days after the inception of the urethritis The day following the onset of the complication, he was given 24 c c antigonococcic serum, and 12 c c the next day This was followed in a few hours by acute retention, due probably to swelling of the posterior urethra, necessitating catheterization There was no temperature rise and no perceptible change in the symptoms of the epididymitis After waiting in vain, the average incubation period, nine days, for the appearance of serum sickness, a third injection of 4 c c was given He developed chills thereafter and a slight itching over the body Forthwith the pain in the scrotum abated somewhat and the swelling subsided materially, but there was no change in the appearance of the urine In five days he was again given an injection of 1½ c c serum Within three hours he developed chills, a generalized urticaria, and joint pains Following this there was a total relief of pain and tenderness in the scrotum, and in forty-eight hours after the last injection the scrotum returned to its normal size Coincident with this improvement, the posterior urethritis disappeared and the second glass in the two-glass test cleared perfectly In the space of three weeks there was complete recovery from the urethritis, with the employment of the usual forms of medication

It is important to note that during the course of serum injections no local or other treatment was employed

With the result of these representative cases in mind, it appeared that whatever effect was produced by the serum was not directly attributable to any true antitoxic or antibacterial elements embodied in the serum, because it in no way resembled the immediate action of diphtheria antitoxin or other antiserum Was it possible that the beneficial results obtained were in reality due to anaphylaxis, or were they favorable phenomena that accompanied the unfavorable allergic symptoms? Could the rise in temperature exert a destructive effect on the gonococcus? It is believed that owing to the high point of temperature equilibrium in the pigeon, for example, a protective influence against infection exists Again, the gonococcus can not withstand high temperature These questions cannot at present be answered, but are still being investigated

To prove that other factors than antibacterial of the specific serum played an important, if not the most important, part was easy Normal horse serum was substituted for antigonococcic serum The following records will show that there was no result obtained with the antigonococcic serum which was not equally well effected with normal horse serum To place the experiment on the same basis throughout, all serums were obtained from the same firm

[2] Herescu and Strominger Verhandl d deutsch Gesellsch f Urol, 1913 and 1914, iv, 102

CASE 4—E C, of the hospital service of Dr Stillians, had developed signs and symptoms of acute epididymitis one month after the onset of the urethritis, and had had no treatment therefor Nine days after the onset of the complication the symptoms were still acute He was then given 10 c c normal horse serum In twenty minutes he became markedly dyspneic, developed swelling of the eyelids, and was in great distress The temperature and pulse were normal These symptoms subsided within an hour Two days later he developed an urticaria, with no temperature rise, and coincident with this all pain, tenderness and swelling of the scrotum disappeared The posterior urethritis cleared completely The patient then passed from observation

This case was rather striking in the rapid onset of anaphylaxis after one injection of serum, with the rapid improvement in the patient's condition Upon inquiry it was learned that he had never before received serums, but was a hostler by occupation, thus accounting for his idiosyncrasy to horse serum

CASE 5—S D, had acute epididymitis on the left side, which had developed two months after the onset of the urethritis Two days later he was given 5 c c normal horse serum, which in turn was followed by 8 and 9 c.c on the two subsequent days Two days after the last injection he developed a generalized urticaria and pruritus There was no temperature rise or other ill effects Upon this day the pain and swelling of the scrotum almost entirely disappeared, as did the posterior urethritis While continuing treatment for the anterior urethritis, along with prostatic massage, he developed an epididymitis on the opposite side two weeks after the healing of the side first affected This was preceded by the redevelopment of the posterior urethritis With caution he was given 1 c c normal horse serum, and in the absence of any ill effects, this was followed by 2 c.c, and this in turn by 5 c c on three consecutive days Slight erythema and pruritus developed after this course, with coincident subsidence of all scrotal disturbance, including a disappearance of the posterior urethritis In two weeks complete recovery was secured

If the serum really provoked or stimulated the formation of antibodies, the concentration of the latter was such as not to afford immunity or protection, after the first administration series, against the involvement of the opposite side, or perhaps the protection was too ephemeral

CASE 6—W A S had gonorrhea of ten weeks' duration, in which time he developed two urethral fistulas and a paraphimosis, and then a right-side epididymitis On the first day of the last complication he was given 10 c c normal horse serum, the second day 12 c c. and the third day 10 c.c There was no change in his condition until six days after the last injection, when he developed hypogastric colic and a slight eruption over the buttocks When seen at this time, the posterior urethritis had resolved and the scrotal condition had improved In three days there was a slight relapse, with recurrence of the posterior urethritis and scrotal tenderness, but upon administration of 4 c c normal horse serum the condition again resolved within twenty-four hours A second relapse occurred in three weeks, whereupon 4 c.c. horse serum were again administered, followed again in twenty-four hours by a clearing up of the posterior urethritis and epididymitis At this stage the patient left town and passed from observation

A review of this case brings to light the interesting data of repeated relapses and improvements, the latter following closely on the administration of small doses of serum The allergic reaction was but slight after the first series, and also after the other injections, yet the change in the patient's condition was marked in each instance

CASE 7—J B had gonorrhea one month when he contracted right-side epididymitis On the first day of the complication he was given 8 c c., on the second, 7 c c, and on the third day, 5 c c normal horse serum Six days following the last injection he broke out into generalized urticaria, with temperature of 100 8, but coincident with that all tenderness in the scrotum disappeared In five days, however, he developed gonorrheal rheumatism in the left knee, with a recurrence of the posterior urethritis, but no more serum was administered Complete recovery was obtained, however, in a month

In this case the effect of the serum, though temporary, nevertheless affirms the corelation of allergic symptoms and improvement

CASE 8—J H had posterior urethritis twenty days, when he developed right-side epididymitis On the second day of the complication he was given 10 c c normal horse serum, and this dose was repeated on the two days following Five days after the last injection an urticarial eruption appeared, and he had a temperature of 101 8 Twenty-four hours later all pain disappeared and the scrotal swelling receded markedly The urine was almost cleared in both glasses, with the exception of threads in the first Within three weeks, with ordinary treatment, including prostatic massage, the patient was discharged as cured

The relation of serum sickness to improvement in this case is so apparent as to require no comment

CASE 9—H F developed a posterior urethritis three months after the appearance of the initial discharge He was given 10 c c normal horse serum, followed the next day with 8 c c of the serum of the patient in Case 6, the latter's blood being withdrawn at the stage of recovery from the first relapse Within eight hours of this dose the urgent symptoms of the posterior urethritis were ameliorated Four days later 2 c c normal horse serum were given This was followed in two days by a florid generalized urticarial eruption, with a temperature of 101.2 Coincident with this reaction, all signs and symptoms of posterior urethritis ceased The second glass of urine completely cleared, while the first was but slightly turbid Pus in the prostate was still abundant, however

In this case the effect of the serum from a convalescent case was very noticeable within a few hours That the influence was not more marked may be attributed to the fact that the donor was not putting up much resistance to the disease, as was evidenced by several relapses, and the protective substances provoked in his blood were insufficient in power or number or both It must be noted, also, that the allergic reaction in this instance was slight The change in the receptor's condition was nevertheless marked The effect of the serum sickness in this patient is noteworthy, for the reason that even with the employment of antigonococcic serum, acute posterior urethritis is usually not benefited

CASE 10—W H Mc, a medical student, developed acute epididymitis one month after the onset of gonorrhea He was then given 8 c c of normal horse serum The next day he developed chills, headache, temperature of 102, and a florid generalized urticarial eruption The day after the onset of these symptoms the urgency of urination began to subside as did the pain in his scrotum The temperature persisted for four days, but then the tenderness and swelling had completely disappeared, the second glass of urine was clear The prostate showed very few pus cells

This case resembled Case 4 somewhat, in that allergy was aroused by one injection of serum, although more delayed It happens that this student is a farmer during vacation In that light his association with horses may explain his susceptibility to horse serum

Case 11—Patient of Dr M S Oliver developed acute posterior urethritis with edema and retention on the fifteenth day of his gonorrhea On the eighteenth day he developed arthritis in the left tarsometatarsal joints and also in the left knee On the twentieth day 10 c c normal horse serum were administered On the twenty-first day a second injection of 10 c c was given, and on the twenty-second day a third 10 c c On the twenty-third day the right knee and ankle became involved This patient had had similar complications with an attack of *gonorrhea two years before, and antigonococcic* serum injections had been of no avail On the thirty-sixth day, in the absence of any serum reaction and any change in his *condition*, 3 c c serum were given In six hours he developed a rash on his face and body, and there was increased pain in the affected joints, but no temperature rise On the thirty-seventh day the joints felt better, but the urine was still cloudy in both glasses On the thirty-eighth day 1 c c horse serum was given and again a rash appeared with increased joint pain, but without temperature rise The thirty-ninth day found the patient with joint pains alleviated and the second glass of urine perfectly clear On the fortieth day 2 c c serum were injected, without provoking eruption or temperature, but causing joint pain, with extension to the finger and shoulder joints The urine remained clear Within a week all joint trouble disappeared, and the urine was still clear

This case is of interest for two reasons first, because of the prolonged period over which the serum was administered without any serious effects, and second, because of the favorable influence exerted by the *serum the days following the injections after the slight* allergic reactions

A summary of these cases discloses the facts that normal horse serum can entirely replace the antigonococcic serum, the content of specific bactericidal properties of which is questionable As a matter of fact, in view of recent work by Warden,[3] it appears doubtful that there are contained any antigonococcic properties in the serum, since in reality merely the metabolic products of the readily autolyzed gonococcus are injected into the horse in the preparation of the specific serum To what factor we can attribute the beneficial results of normal horse serum, we cannot definitely state That allergic phenomena play a rôle seems evident, since the best results were obtained at the time of the onset of serum sickness, and the greater the reaction the better the result An attempt at explanation of this factor leads into the depths of the study of the nature of anaphylaxis It is possible that certain elements in the serum itself exert a favorable influence This has been found true, as before mentioned, in other infectious diseases, in which, too, the blood of convalescents has proved of great value A suggestion of this influence was noticed in the patient of Case 9

As investigation along this line is still being conducted, we can at this time offer nothing more than evidence sufficient to favor normal horse serum in place of antigonococcic serum, whose value as a specific is questionable If allergy is in reality of therapeutic value, its employment is nevertheless hazardous It is a question whether any gonorrheal complication requires the use of such heroic treatment Safety cannot be sacrificed for speed

A STUDY ON FOOD

AND THE FUEL VALUE OF THE DIETARY AT THE NEW YORK CITY MUNICIPAL SANATORIUM

ROBERT J WILSON, M D
Director of the Bureau of Hospitals, Department of Health
AND
WALTER L RATHBUN, M D
Physician in Charge, New York City Municipal Sanatorium
NEW YORK

The dietary question is fraught with many difficulties in an institution for the treatment of tuberculosis, and is a problem which is never entirely solved Just when the responsible party is congratulating himself on a satisfactory, as well as an economical solution of the proposition, trouble appears from the most unexpected sources, varying from a bug in the cereal to a jump in the cost per capita During recent years the consensus of opinion has changed from superalimentation in tuberculosis to the more rational procedure of feeding three generous meals a day, with extra diets only when indicated by poor appetite at the meal periods, accompanied by a markedly substandard or steady loss of weight Some patients with poor appetites will eat as much as usual during meal periods, even if given extra between-meal diets, and when the nourishment is required and well borne, its administration is indicated However, if the total caloric intake is not increased, the extra diets should be discontinued

It has been pointed out by competent observers, notably by King and Bardswell and Chapman, that the strain of forced feeding on the organs of assimilation and elimination is so great that it becomes a source of danger rather than benefit in many cases, and its use should be the exception rather than the rule While this is generally true, I have observed many patients who were capable of assimilating enormous quantities of nourishment without any apparent primary or secondary deleterious effects on their organisms I believe, however, that conservatism should play a large part in the feeding of the tuberculous, and as the disease generally persists for a long period, the gastrointestinal tract and kidneys should be spared all extra strain, if they are to be expected to continue a successful struggle after the first acute onset of the disease has been overcome The patient who emerges from the preliminary fighting with a damaged gastro-intestinal tract is in an unfortunate position, with poor prospects of becoming a comfort to himself or a permanently self-sustaining member of the community His chances for an early exacerbation are excellent, *and* for final recovery, to say the least, are compromised It seems only rational that the stomach should have a maximum amount of rest after a heavy meal, and for this reason alone the routine administration of milk and egg diets between meals would seem to be strongly contraindicated In this connection, I should like to mention Dr E S McSweeny's interesting studies at Otisville in 1908, for they are very convincing, and established the point just made as applied to patients in the Municipal Sanatorium At that time reports from other institutions[1] indicated a number of objections to forced feeding, but it was felt that possibly some of these reasons did not necessarily apply at Otisville, where all afebrile patients are compelled to do a certain amount of work

---

[1] Newton, R C The Diet and Regime in Vogue in Thirty Four Tuberculosis Sanatoria, Proc Sixth Internat Cong, Part 2

McSweeny's experiment was as follows

Two groups of patients were selected Group 1 was allowed milk and eggs in addition to the three meals, while Group 2 received only three regular meals daily It was found that the patients in Group 2 (those who ate only three regular meals) averaged larger weight increases than those in Group 1 It was decided to discontinue the milk and egg diets that had been administered as a routine morning and afternoon since the institution was opened, and to depend on the regular meals in all but exceptional cases This policy was proved, by later experience, to be sound, and has been continued to date

A study of the caloric content of our dietary was carried out at the Women's Unit in 1910, but the results were not published The work was resumed two years ago and, owing to the paucity in the literature of studies in connection with the dietaries of tuberculosis institutions, it was decided to publish our results with the hope that such a step would promote discussion and criticism along this line It was felt that so important a function as the dietary, which is one of the fundamentals of sanatorium treatment, deserves more comprehensive and collective study than it has received in the past, and that an exchange of ideas by the various workers in tuberculosis institutions is particularly desirable, for such an exchange will not only tend to lead to economy in administration, but will eventually provide a scientific basis on which to construct the future dietaries Dettweiler said, "My kitchen is my pharmacy," and Osler[2] is quoted as follows "As a healing of tuberculous process is largely dependent upon the state of nutrition, the question of diet becomes of the very first importance"

In spite of the fact that the dietary has been recognized for many years to be of prime importance, one finds but few studies, by men in this country, of a character that deserve more than passing attention It seems deplorable that so little effort has been expended in this field during the past eight or ten years while the tremendous activities in connection with other phases of the tuberculosis problem have been in progress Nothing tends to conserve the provision supply to such an extent as an active interest in the actual amount by weight of food consumption and food waste

The aim of those in control of institutional dietaries should be (1) to supply the food needs of the patients as economically as is consistent with the quantity, quality and service required for the treatment of the disease from which the patients suffer, (2) to avoid too frequent repetition of any particular foodstuff, and (3) to keep a close check on the amount of plate, general table, kitchen and ice box waste When our dietary studies were resumed in 1914, we were guided by these principles

The most costly item of the dietary is meat, and this was our first point of attack It was found that egg breakfasts were entirely satisfactory to the patients, therefore eggs were served in various styles for from four to five of the morning meals each week Steak and chop breakfasts were entirely eliminated, and other meat orders were gradually cut down to the minimum The per capita per diem consumption of meats and fish fell from an average of 19 9 to 14 5 ounces during the course of six months The eggs which are used for cooking purposes at the Municipal Sanatorium are of cold storage variety (fresh gathered extra), and are contracted for (1915) at from 25 5 to 26 cents per dozen These are recandled after delivery to the institution The substitutions above referred to and the routine serving of small initial meat orders, which cuts down the plate waste of those who have small appetites, but who, on general principles, take a large slice of meat when it is immediately available, accomplished the reduction in meat consumption and was mainly responsible for lowering our cost per capita for foods from 42 cents for the first nine months of 1913 to 37 + cents for the same period in 1914 (Table 1) Care was taken to keep the average number of calories up to a reasonable standard, and that this was satisfactorily accomplished is indicated by the fact that our patient weight reports continued to be entirely satisfactory

TABLE 1—SAVINGS FOLLOWING SUBSTITUTION OF EGGS FOR MEATS AT BREAKFASTS COVERING A PERIOD OF FOUR WEEKS

No of Meals	Variety of Food	Per Meal	Total	Price cts (1914)	Cost
8	Steak	260 lbs	2 080 lbs	20 per lb	$416 00
8	Chops loin	145 lbs	1 160 lbs	19.3 per lb	223 83
	Chops rib	125 lbs	1 000 lbs	10 per lb	100 00
Total for meat					$739.83
16	Eggs	80 doz	1,280 doz	23 6 per doz	302 03
Total savings for period of four weeks					$437 80

We have felt for several years that it is not only entirely unnecessary, but also undesirable to serve meat and eggs at every meal, in fact, in 1910 meat and eggs were eliminated from the breakfasts at the women's unit for several weeks During this time the weight increases and general physical condition of the patients were entirely satisfactory In September, 1915, after an explanatory talk with the patients at the women's unit, it was decided to substitute 8 ounces of milk per capita for eggs on four mornings in the week, and this has not only proved to be a satisfactory change, but has, in addition, resulted in a weekly saving of 11 3 cents per patient per week

TABLE 2—COMPARATIVE FOOD VALUE AND COST OF MILK AND EGGS

		Protein	Fat	Carbohydrate	Total Calories	Cost per Capita per Diem
Eggs 2 per portion	Grams	18 50	10.54			(Eggs 26 cts per dozen) 4.33 cts
	Calories	55 81	105 46		161	
Milk ½ pt per portion	Grams	7 48	9 08	11 34		(Milk at 6 cts per qt) 1 5 cts
	Calories	30 66	84 44	46 49	162	

Saving per capita per diem when milk is substituted 2.83 cents

Table 2 demonstrates that by substituting milk for eggs it is possible to save $16 41 a day in an institution of 580 beds (the capacity of the Municipal Sanatorium) without changing the caloric value of the dietary If this substitution was made on four mornings each week, the annual saving would be approximately $3,500 Another factor of importance in connection with the substitution of milk is that good milk is easily procurable (at least in this vicinity) at 5 5 cents a quart at all seasons, while satisfactory eggs are very often unobtainable, in sufficient quantities, at any price A further result was an increased consumption of cereal, which we feel is particularly desirable and which has practically no effect on the cost per capita The breakfast menu on the four days referred to consists of milk, 16 ounces, a good variety of hot cereal and rolls, butter, coffee, and occasionally fruit

---

[2] Friedenwald and Ruhräh Diet in Health and Disease

A factor worthy of mention in connection with the utilization of our meats, which applies more especially to the women's unit, is the large children census We have seventy-two children, between the ages of 5 and 14 years, and all of the meat which cannot be served to adults in the form of slices is cut up into small pieces and served to our juveniles Table 3 represents the amount of carving waste which is eliminated by this procedure, and demonstrates to some extent the advantage, from the standpoint of economy, of treating small children in institutions with adults

TABLE 3—COMPARISON OF CARVING WASTE AT MALE AND FEMALE UNITS, NOV 1 to 7, 1915

Variety	Male Unit		Female Unit	
	Amount Received from Storehouse, Pounds	Carving Waste, Pounds	Amount Received from Storehouse, Pounds	Carving Waste, Pounds
Roast beef	167	14	96¾	1½
Corned beef	203	44½	95	12½
Roast lamb	182	19	94½	5
Pot roast	164¼	27	99½	2½
Boiled ham	138½	33½	63	13

Much of the roast meat which is close to the bone and which is of fine quality is available for this use The utilization of "left overs," which are bound to be ever with those who serve large numbers of persons, is a hard problem to handle in a state, county or municipal tuberculosis institution, where the stay is for a comparatively long period and where those who are catered to are posessed of their normal amount of gray matter, in addition to a highly specialized sense of their rights as citizens and former tax payers Many economical and delectable dishes of high food value which are prepared from "left overs" and which are eaten with relish in most well to do households are scouted by a large majority of the patients Those culinary connoisseurs have very definite ideas on the subject of dietetics, and as their forcefully expressed likes and dislikes are the governing factors in the formation of the institutional menu, it behooves the food purveyor to watch that infallible barometer, the garbage can, with ever increasing interest, and to catch the rumblings of any approaching storm from the distance This precaution often saves the situation before any real serious developments occur, and, besides, keeps the responsible party in a continual state of preparedness In our experience, hash has always been mistrusted in spite of the excellence of its ingredients, and it became necessary for us to discontinue it over two years ago, after our unsuccessful efforts to please with various "hashy" combinations had been paraded before the Board of Estimate through the agency of a former patient The patients gave abundant evidences that they would not eat it, and although the "hash meal" was an economy, it was felt that it did little to further the results of treatment, so it was stricken from the menu It is easy to carry economy too far in the planning of an institutional dietary It is also necessary to bear in mind the fact that the physical well being of the patients is of first importance, and that no one thing tends to cause more dissatisfaction among the patients than an unsatisfactory menu

The most reliable criterion for checking up the adequacy and esthetic qualities of the dietary is a computation of the actual food consumption and its value in calories, combined with a careful per capita study of the plate waste If the number of calories is up to the standard, the food waste low and there has been a dearth of justifiable complaints, the person or persons responsible for the dietary can rest assured that all is well

TABLE 4—PER CAPITA CONSUMPTION OF FOODS AT BOTH UNITS AMONG THE VARIOUS CLASSES OF PATIENTS

	Adults				Children					
	Men	%	Women	%	Boys 9-15 Yrs	%	Girls 5-9 Yrs	%	Girls 10-14 Yrs	%
Protein (grams)	127 2		107 4		105.5		84.9		91 9	
Fat (grams)	154 5		121.8		129		99 3		102 3	
Carbohydrates (grams)	425 7		288 9		413.88		254 4		267	
Protein (calories)	521	14	440	16	432	13	348	15	376	15 5
Fat (calories)	1 436	39	1 132	41	1,199	36	923	40	951	39 5
Carbohydrates (calories)	1 745	47	1,184	43	1 696	51	1 043	45	1,094	45
Average calories per diem	3 700+		2,750+		3,300+		2,300+		2,400+	
Average number calories per pound of body weight	27		28		43 5		33.8		34 5	

Calories for male and female adults combined, 3,200

Table 4 presents one of our dietary studies In Table 5 are given King's and Bardswell and Chapman's diets It will be seen that our protein content is considerably lower than Bardswell and Chapman's, and slightly lower than King's, the fats are lower than Bardswell and Chapman's, and higher than King's, and the corbohydrates about equal to King's, while much higher than Bardswell and Chapman's Our dietary, however, is giving excellent satisfaction with a minimum of gastro-intestinal disturbances, and the comparative results tend to show that no trouble may be expected so long as the protein, fat and carbohydrate content of a dietary is kept within certain bounds

TABLE 5—KING'S AND BARDSWELL AND CHAPMAN'S DIETS

	King's Standard Diet Annex,* Grams	Bardswell and Chapman's Standard Diet,† Grams
Protein	131	144
Fats	113	160
Carbohydrates	385	270
Calories	3,166	3,180

* King The Construction of an Economic and Efficient Diet in Tuberculosis Tr Nat Assn S and P Tuberc, 1909

† Bardswell, N D and Chapman, J E Diets in Tuberculosis New York, Oxford University Press, 1908

It has been stated that children require 80 calories per kilogram (36 calories per pound) of body weight, and adults, moderately active, from 35 to 40 calories per kilogram (16 to 18 + calories per pound) of body weight[3]

Rubner's figures for a man of 65 kg (140 pounds) are given in Table 6

TABLE 6—RUBNER'S FIGURES FOR A MAN OF 140 POUNDS

	Total Calories	Calories per Kg of Body Weight	Calories per Lb of Body Weight
During rest in bed	1,800	28	13
In repose	2 100	32	14½
Light work	2 300	33	15
Moderate work	2 600	40	18+
Hard work	3 100	48	22

Our average for men, 26 calories per pound of body weight, is well above the figures given for men at hard work, and the average for women about equal to it The male children consume far above the average calories per pound as given by Pattee, and the female children slightly less than her figures It would seem as if from 3,100 to 3,200 calories is about the normal average for the mixed sexes in tuberculosis institutions, as our food consumption was controlled entirely by the appetites of the various patients, and I presume that such was the case in the other institutions mentioned above

If this premise is true, then the ability of the various patient groups to select the amount and variety of food necessary to yield what is considered to be the proper number of calories from entirely different dietaries is remarkable, and confirms the experiences of other observers in this field In contrast to these figures, the reader may be interested to learn that Fisher gives 300 calories as a hypothetic figure for the amount of protein needed in the diet of the tuberculous or, as he states, 50 per cent more than is required for a healthy man In answers to a questionnaire which he sent to fourteen tuberculosis institutions in this country and abroad, it was found that the number of calories furnished by the various dietaries varied from 410 to 1,200 for protein, from 750 to 2,200 for fat, and from 560 to 2,100 for carbohydrates In thirteen institutions the number of calories of protein exceeded 500, in thirteen the number of calories of carbohydrates exceeded 1,100, and in twelve the fats ranged from 1,100 calories up The calories varied from 2,400 to 5,500 in all, ten institutions averaging 3,500 calories and up[4]

CALORIES PER POUND OF BODY WEIGHT

As might be expected, the number of calories consumed per pound of body weight was found to be much greater in children than in adults, but we were surprised by the marked excess of calories consumed by the group of male children between the ages of 9 and 14 years over the female group of the same ages, which amounted to 10 calories per pound of body weight The average gain in weight, however, was 1¼ pound for the female group and 73/100 for the male group This may be accounted for by the greater activity of the boys, although one would think that the excess of calories consumed by them should be sufficient to neutralize the effect of this activity to some extent A study of the weight records of the male and female units covering four years is of interest in connection with the foregoing These units are separate institutions so far as the records are concerned, and our opportunity for watching the weight increments of the two sexes is peculiarly favorable It will be seen that our records prove conclusively that the capacity for accumulating weight is markedly in favor of the females in spite of the monthly menstrual drain, and is enough to lead us to believe that it is a characteristic of the female sex I believe it is the general opinion that males gain more on the average than females, and our studies have shown that the consumption of calories per pound of body weight by males is in excess of that of the female sex 27 calories per pound for men and 24 for women In spite of the greater tissue bulk in males with the capacity for greater food consumption, our results prove that females gain the most weight

REPETITION OF FOODSTUFFS

Care in the avoidance of repetition has been the saving grace of many splendid culinary combinations No matter how infatuated patients may be with a certain foodstuff, if it is served too frequently their ardor will soon wane, and a good thing is lost to the menu Much of the monotony of the institutional dietary is due to repetition, and the fact that the menu is not so varied as to prevent patients from making a fair guess as to what they will receive at a certain meal on a certain day With this in mind, about two years ago, we constructed a four weeks' menu which covered all of the foodstuffs available on our yearly contract During the late spring, summer and early fall months, we have an abundance of green vegetables from our garden, and these are added to our menu as they are produced We have from one to two vegetables besides potatoes for dinner and supper For the first four weeks of operation the menu starts with the first week and ends with the fourth, for the second four weeks it commences with the second and ends with the first week, for the third four weeks, it begins with the third week and ends with the second, etc This arrangement makes it practically impossible for any patient to surmise what food is to be served at any time Moreover, the plan facilitates the ordering of supplies, and enables one to work out a daily ration with very little difficulty

TABLE 7—WEIGHT

		Average Increase of Those Gaining Pounds	Gained		Lost	
			Number	Per Cent	Number	Per Cent
1912	Male unit	7 15	419	80 11	104	19.89
	Female unit	12.23	276	91.39	26	8 61
1913	Male unit (adults)	9.84	357	83 02	78	16.98
	Male unit (children)	5.21	48	97 96	1	2 04
	Female unit (adults)	13 48	228	87 36	33	12 64
	Female unit (children)	10 03	106	96.36	4	3 64
1914	Male unit (adults)	9 46	305	78 41	84	21.59
	Male unit (children)	7.20	39	97 50	1	2 50
	Female unit (adults)	10 71	200	83 68	39	16 32
	Female unit (children)	10 25	104	96 30	4	3 70
1915	Male unit (adults)	10 62	350	85.37	60	14 63
	Male unit (children)	9 48	36	97 30	1	2 70
	Female unit (adults)	11 69	232	85 29	40	14 70
	Female unit (children)	11 49	70	97.22	2	2 78

Our experience has taught us that it is good judgment to stop for a while, at least, any particular combination that the patients begin to tire of A good illustration of the evil of repetition is our experience with codfish balls at the men's unit several years ago, where it had been customary to serve them about four times each month It is a cheap meal, and was appreciated by the patients for a time, but they finally developed a marked aversion to salt cod, and on one occasion a few outraged "citizens" waylaid a whole meal of carefully prepared uncooked codfish balls and threw them into the refuse pail The miscreants were apprehended and punished, but nevertheless the hint was taken and salt codfish did not appear on our menu again for a considerable period It is now alternated with other salt fish and is appreciated

PLATE WASTE

The work reported by Wright on plate waste is of value to those employed in insane hospitals, but of practically no use to workers in tuberculosis institutions It is to be expected that the per capita waste will be greater in a tuberculosis institution than in an institution for the care of insane or in an acute hospital, owing to the fact that much larger quantities of food, a great deal of which is especially rich in wastage, is served to the tuberculous Meats furnish an especially large amount of waste, owing to the comparatively large percentage of uneatable portions, such as gristle, fibers, small bones, etc, and this food forms a conspicuous part of the dietary of the sanatorium We have no means of checking up our waste with that of other institutions for the treatment of tuberculosis, as our review of the literature has failed to reveal any studies on this problem We feel that periodic studies of the per capita food wastage will do much to stimulate those in charge of the dietary to further efforts toward economy, and are sure that the result of food waste studies by the various large sanatoriums would be of great service to all Our dietitians are instructed to serve as much of any particular food as a patient desires to eat, but to reduce useless waste to a minimum by serving it in small portions This rule has proved to be satisfactory to the patients, and is bound to effect economy of foodstuffs

TABLE 8—AVERAGE PERCENTAGE OF MEAT CONSUMPTION AND SHRINKAGE

Meat	Consumption, Per Cent	Shrinkage and Wastage, Per Cent
Roast beef	36 to 39	64 to 61
Pot roast	28+	71+
Beef steak sirloin	25 5	74 5
Roast lamb	29 5	70 5
Lamb chops	31	69
Liver	44 5	55 5
Roast chicken	26	74
Bacon, fried	30 5	69 5
Salt pork	54	46

Our average per capita per diem waste of solid foods is for male adults, 45/100 pound, for boys from 9 to 15, 27/100 pound, for females, entire dining hall, 41/100 pound, and for female children, 335/1000 pound It is noticeable from this that children "clean their plates" much better than adults, although the smaller amounts served accounts for a part of this

In connection with our plate waste studies we carried on investigations covering the shrinkage in meats, which were followed up from the time the meat was cut from the side of the carcass until the remnants were accounted for as plate waste

The following headings used in our tables illustrate the method of procedure

Date
Varieties of meat
Amount received from storehouse, including butchering waste, pounds
Kitchen trimmings, pounds
Weight before cooking, pounds
Shrinkage, pounds
Plate waste, pounds
Surplus, pounds
Amount consumed, pounds
Percentage of consumption

We found that the percentages given in Table 8 represented the average percentage of meat consumption and shrinkage (including wastage) These percentages of consumption seem to be absurdly low, but when we consider the butchering waste, the large amounts of water and fat which are eliminated by the cooking, and the weight of the bones, fiber and gristle, which appears as plate waste, the figures assume more reasonable proportions

TABLE 9—FORM OF TABLE FOR COMPUTATION OF DAILY CALORIES AND FOOD WASTE *

Date									
Menu for Day	Pounds Eaten	Chemical Composition			Number of Pounds Eaten			Plate Waste	Space Used for Computing Number of Calories
		% P	% F	% C	P	F	C		
Column for various foods		Percentage not totaled			These four columns are totaled				
Total No of pounds									

* *Abbreviations P, protein F, fat, C carbohydrate*

Method of procedure for computing number of calories in dietary

Number of pounds of protein plus number of pounds of carbohydrate × 1,820 (number of calories in 1 pound of protein or carbohydrate) = total number of calories of protein and carbohydrate

Number of pounds of fat × 4,080 (number of calories in 1 pound of fat) = total number of calories of fat

Total number of calories of protein and carbohydrate plus total number of calories of fat = total calories consumed for day

Total calories consumed for day ÷ number of persons served = average calories per patient per day

Total pounds of plate waste ÷ number of persons served = average per capita plate waste per day

ROUTINE FOR DETERMINING THE CALORIC VALUE OF FOOD

Our routine for determining the caloric value of the food served, which is similar to that in general use, except that we do not use the metric system, follows

The various classes of foods are weighed separately before service After the meal is finished all of the foods which are suitable for future use (such as meats on the platters, etc), are weighed separately and the weights deducted from the original amounts The foods which are left as "plate waste" are now separated out and placed in marked containers (one for each article), which are weighed individually The original amount served minus the "left overs" minus the "plate waste" equals the actual amount of food consumed It is, of course, necessary to determine the percentage of protein, fat and carbohydrate in each combination of foodstuffs served, and this is very easily accomplished as tables are available which cover almost every possible ingredient The amount of protein, fat and carbohydrate is determined by multiplying the number of pounds of each foodstuff on the daily menu by its percentage of protein, fat and carbohydrate, and totaling the three separately The total number of calories for the day is obtained by multiplying the number of pounds of protein and carbohydrate consumed by 1,820, as both of these have the same caloric value, and the number of pounds of fat by 4,080 The results are then added and the sum represents the number of calories consumed The total number of calories, divided by the number of persons served for the day, gives the average number of calories consumed per person Table 9 is used at Otisville for the computation of the daily calories and food waste The calories are figured out for each meal and then totaled

CONCLUSIONS

1 In all institutions for the care of the tuberculous, food studies, including the caloric content of the dietary and food waste, should be carried on at regular intervals, preferably for one week or more during the various seasons of the year, and these records should be made available for comparative purposes

2 Special training, though advisable, is not a necessary requisite for the carrying out of a successful dietary study in an institution It is, of course, essential that the doctor who directs the work should be thoroughly familiar with the problem It is only necessary that the person or persons who are doing the work should be intelligent, careful and willing to follow conscientiously the "rules of the game"

3 The elimination of meats and eggs from the morning meal and the substitution of milk is a sound and justifiable economy

4 The dietary of the tuberculous should be high in caloric value, but confined to three daily meals in all but exceptional cases

5 Males consume more food than females, both in total amount and in number of calories per pound of body weight, but in spite of this fact, females make much larger gains than males, enough so as to indicate that rapid accumulation of weight is a characteristic of the female sex

Diagrammatic scheme for computing the caloric content of a dietary Pounds are converted into grams by multiplying by 453 5925

6 The avoidance of frequent repetition of foodstuffs is very important

7 A four weeks' menu, when used as suggested, is of great aid to those controlling the dietary, and tends to do away with repetition

8 The treatment of small children, in separate units, in institutions with adults, is both feasible and advantageous in that it results in economy of foodstuffs

9 Small initial servings with as many "seconds" as may be desired is satisfactory to the patients and prevents much plate waste

10 The plate waste in institutions for the tuberculous is of necessity higher than in hospitals for the insane or in general hospitals

Much credit is due to Miss Marguerite Brady, who has been in charge of the dietary work at the male unit since the work was started and to Miss Carlotta Nellis, Miss Beatrice Cummings and Mrs Catherine Stoltzenberg, who served in turn as dietitians at the female unit We wish to express our thanks to Dr Herbert M King for his assistance, to Graham Lusk for reviewing the results of our work, and to Miss Charlotte Strickland of Loomis Sanatorium for many useful suggestions

VARIATIONS IN RENAL FUNCTION DEPENDENT ON SURGICAL PROCEDURES *

DONALD F CAMERON, AM, MD
Fellow in Surgery, University of Minnesota
MINNEAPOLIS

This report is based on the investigation of changes in renal function produced by operations performed under general anesthesia, and of the variations in renal activity dependent on relief from back-pressure of urine For this work, the rate of excretion of phenolsulphonephthalein and the concentration of urea in the blood have been taken as the indexes of renal activity These tests were chosen because of their recognized value and because they are so easily performed The phenolsulphonephthalein test was carried out by the technic of Rowntree and Geraghty[1] The determination of the urea concentration in the blood was made by the urease method introduced by Marshall[2] The concentration of total nonprotein nitrogen in the blood is probably a better index of renal efficiency, but the urea determination is made with less difficulty and can easily be made a routine clinical procedure It is true that the proportion of urea nitrogen in the total nonprotein nitrogen varies considerably, but usually it forms from 50 to 70 per cent of the nonprotein nitrogen, the percentages increasing with the total nitrogen retention This has been shown by Folin and Denis,[3] Foster,[4] Christian, Frothingham, O'Hare and Woods[5] and others In infants the urea nitrogen percentage is appreciably lower as a rule, according to the results obtained by Schlutz and Pettibone[6] But on the whole the concentration of the urea in the blood may be taken as a fair index of renal function

Although the question as to the agreement of phenolsulphonephthalein and blood urea tests is beyond the scope of this paper, still Table 1, giving the results of these two tests performed simultaneously on the same patient, is of considerable interest

Throughout these tables blood urea concentration is reported in milligrams of urea per hundred c c of blood Of the phenolsulphonephthalein figures, the first represents the time in minutes elapsing between the injection of the substance intramuscularly and its appearance in the urine, the second figure is the percentage excretion in the first hour after appearance in the urine, and the third figure is the percentage excretion in the second hour For the arbitrary grouping, a phenolsulphonephthalein excretion of less than 50 per cent in two hours is considered "diminished,"

and a blood urea of fifty or over is considered "increased"

In the consideration of the foregoing results, it is to be noted that the patients on whom these tests were made were persons suffering from some surgical disease of the urinary tract, that their average age was about 55, and that all grades of arteriosclerosis are represented With the exception of the patient in Case 29, no other showed any signs of cardiac decompensation or edema With the exception that a considerable number of patients who had high phenolsulphonephthalein excretions did not have a blood urea test made and so are not reported here, there was no selection of cases for Table 1

TABLE 1—RESULTS OF PHENOLSULPHONEPHTHALEIN AND BLOOD UREA TESTS

GROUP I, WITH APPROXIMATELY NORMAL PHENOLSULPHONEPHTHALEIN EXCRETION AND BLOOD UREA CONCENTRATION

Case No	Phenolsulphonephthalein Time	1st Hour	2d Hour	Blood Urea
1	10	58	14	28
2	10	42	15	34
3	10	45	19	43
4	10	45	10	36
5	8	52	17	30
6	10	40	20	42
7	10	52	10	34
8	10	45	15	36
9	11	40	22	56
10	9	28	28	44
11	9	40	18	31

GROUP II, WITH DIMINISHED PHENOLSULPHONEPHTHALEIN EXCRETION, BUT WITH APPROXIMATELY NORMAL BLOOD UREA

Case No	Phenolsulphonephthalein Time	1st Hour	2d Hour	Blood Urea
12	13	25	21	39
13	34	16	11	53
14	20	17	7	53
15	17	19	17	42
16	10	18	24	32

GROUP III, WITH DIMINISHED PHENOLSULPHONEPHTHALEIN EXCRETION AND INCREASED BLOOD UREA

Case No	Phenolsulphonephthalein Time	1st Hour	2d Hour	Blood Urea
17	21	7	12	94
18	18	12	10	105
19	33	8	9	91
20	18	12	11	83
21	25	Trace	Trace	205
22	20	5	6	164
23		Trace	Trace	430
24		Trace	Trace	290
25	32	9	10	90
26	15	8	10	89
27	8	25	18	80
28	11	21	14	62
29	18	6	9	84
30	32	9	10	90

In looking over the results obtained in this series of cases, one will notice that a high phenolsulphonephthalein excretion was always associated with a normal or only slightly increased blood urea concentration, and that a low phenolsulphonephthalein excretion was usually associated with a very definite increase in blood urea concentration, although in a small number of cases the blood urea was not much increased, if at all (Group II)

The foregoing conclusions in the main are in agreement with those of most investigators, however, it is known that discrepancies are encountered somewhat more frequently when the tests are performed on patients suffering from the various forms of nephritis complicated by cardiac decompensation, with chronic passive congestion and edema For further comparison of these tests see the work of Frothingham and Smillie,[7] Rowntree, Marshall and Baetjer,[8] and of Hopkins and Jonas[9] It is interesting to note that the four cases of superpermeability reported by Baetjer[10] showed normal or only moderately increased nonprotein nitrogen with the hypersecretion of phenolsulphonephthalein

FUNCTIONAL CHANGES FOLLOWING RELIEF FROM BACK-PRESSURE OF URINE

It is well known that an increased phenolsulphonephthalein excretion and a decreased nonprotein nitrogen retention are usually associated with improvement in renal function But nowhere is this change so well shown as in persons relieved of some form of urinary obstruction In Table 2 is shown the result of preliminary treatment of patients with urinary obstruction due to prostatic hypertrophy The treatment consisted in bladder drainage by means of an inlying catheter Most of the patients were able to be up in chairs or walking about during the period of this treatment In most cases there was very little or no change in the physical signs

In Table 2 the determinations on each patient were made at intervals of from four to seven days, the corresponding phenolsulphonephthalein and blood urea tests being made approximately simultaneously Similar tests, made on quite a number of other patients who did not have so high an initial nitrogen retention, showed exactly similar but less marked changes It is also worthy of note that a fall in blood pressure generally accompanied the improvement in condition, in Case 1 the blood pressure dropped from 210 to 155 mm Hg Excepting in Case 4, the patients whose tests are given in Table 2 were all operated on, a prostatectomy being done, and all recovered normally with no uremic symptoms In Case 4 the patient was very drowsy on admission, his mental condition, however, improved markedly, but he was considered too poor a risk for operation

TABLE 2—RESULT OF PRELIMINARY TREATMENT OF PATIENTS WITH URINARY OBSTRUCTION DUE TO PROSTATIC HYPERTROPHY

	Phenolsulphonephthalein Time	1st Hour	2d Hour	Blood Urea
Case 1	21	7	12	94
	15	19	10	72
	12	23	15	64
	13	23	12	47
Case 2	18	12	10	105

	19	18	15	64
	15	24	11	55
Case 3	33	8	19	91
	18	26	25	53
Case 4	25	Trace	Trace	205
	20	Trace	Trace	200
	25	Trace	Trace	158
Case 5	32	9	10	90
	34	16	11	53
	20	17	7	53

During this preliminary treatment the patients received the routine hospital diet, which contains the normal amount of nitrogenous food Folin, Denis and Seymour,[11] Frothingham and Smillie[12] and others, have shown that marked changes in the nonprotein nitrogen of the blood may be produced by variations in the nitrogenous intake But the changes recorded occurred while the patients were on the same diet The great importance of these tests in the selection of the most opportune time for operation is obvious, for often there is very little or no change in the appearance of the patient or in the physical examination or urine analysis

EFFECT OF ANESTHETIC AND OPERATION ON BLOOD UREA

1 Nitrous Oxid-Oxygen-Ether Anesthesia, with Rebreathing Very little ether was used, occasionally none at all, and never so much but that the patients were conscious in five or ten minutes after operation The blood urea determinations were made twenty-four hours or less before operation, and again from twenty-four to forty-eight hours afterward, and on some of the patients subsequent determinations were made at three and five day intervals The results are shown in Table 3

TABLE 3—BLOOD UREA FINDINGS WITH NITROUS OXID OXYGEN ETHER ANESTHESIA, WITH REBREATHING

Case No	Operation	Blood Urea Before	Blood Urea Afterward	Subsequent Determinations
1	Excision of sinus tract to kidney	28	38	
2	Nephrectomy	34	44	
3	Nephrectomy	43	68	
4	Pyelotomy	36	70	
5	Prostatectomy	30	59	
6	Prostatectomy	64	87	
7	Prostatectomy	47	57	
8	Prostatectomy	53	48	
9	Nephrectomy	79		192 202 159 104 53
10	Nephrectomy	63		130 170 104 79
11	Vesical lithotomy	181	227	262 300 413
12	Prostatectomy	47		198 103,67
13	Prostatectomy	49	76	

In Table 3 it will be noticed that all patients except one showed a more or less marked rise in blood urea immediately following the operation, the average being 21 mg per hundred c c This increase must be considered all the more real when it is remembered that immediately after operation each patient receives from 1,000 to 1,500 c c normal salt solution infusion, and that they are all on a very low protein diet for at least forty-eight hours after operation The average age of these patients was about 50 The kidneys which were removed had all been shown previously by separate phenolsulphonephthalein tests to have markedly diminished function For some reason not obvious, the patients in Cases 9, 10 and 12 developed a very high nitrogen retention after operation They showed definite but not marked uremic symptoms All recovered except the patient in Case 11 This patient was moribund on admission A chronic and extreme grade of urinary obstruction due to a vesicoprostatic calculus developed suddenly into a complete obstruction, and the patient died following an emergency suprapubic cystostomy

2 Ether Anesthesia, Open Method From the nature of the operations in Table 3 it is evident that only the first six cases of Table 4 are comparable with the former These six cases show an average increase of 13 mg urea per hundred c c of blood following operation, compared with an average of 21 mg increase in the former series The remainder of the series in Table 4 shows an average increase of 9 mg per hundred c c blood, although here it is not unusual to meet with cases showing a slight decrease even in the blood urea In very few of the cases from 7 to 25 was any infusion of salt solution given A routine infusion as was given the patients reported in Table 3 would doubtless have lowered still more the slight increase in blood urea The average age of these patients, exclusive of the first six, was about 35 It is interesting to note that the patient in Case 16 who showed a 34 mg rise was in profound shock for some time during and after the operation His blood pressure fell to 40, but later was kept at about 90 by intravenous infusion of salt solution with epinephrin Cases 18 and 19 represent the effect of anesthetic alone and anesthetic with operation on the same patient At the first attempt satisfactory anesthesia could not be induced, although the patient was incompletely anesthetized for over an hour, and a slight decrease in blood urea resulted Two days later a craniotomy was performed, requiring four and a half hours The blood urea was only slightly increased From this table it is seen that in persons suffering from the ordinary surgical diseases there is, as a rule, only a slight, if any, increase in blood urea concentration following an operation under ether anesthesia Even in those patients undergoing an operation on the urinary tract in whom, on account of the age and the nature of the operation, one finds, as a rule, the maximum postoperative rise in blood urea, in this small series of cases, at least, this rise was not as high as that observed in similar cases in which nitrous oxid-oxygen-ether anesthesia was employed This series of cases is evidently too small to serve as the basis for very positive conclusions, but it may be stated that the results obtained here fail to support the contention that nitrous oxid-oxygen-ether anesthesia has a less deleterious effect on renal efficiency than has a pure ether anesthesia

TABLE 4—BLOOD UREA FINDINGS WITH ETHER ANESTHESIA, OPEN METHOD

Case No	Operation	Blood Urea Before	Blood Urea Afterward

24	Gilliam	34	35
25	Hernia	37	58

The effect of operation under gas and ether anesthesia on phenolsulphonephthalein excretion has been studied by Sanford,[13] Block[14] and Miller and Cabot [15] There is a general agreement that, as a rule, there is a definite decrease in phenolsulphonephthalein excretion after ether anesthesia, the decrease varying roughly with the amount of anesthetic and length of operation

---

[13] Sanford Cleveland Med Jour 1912 xi 763

[14] Block F B The Effect of Operation on Kidney Excretion as Indicated by the Phenolsulphonephthalein Test THE JOURNAL A M A April 25 1914 p 1309

[15] Miller R H and Cabot Hugh The Effect of Anesthesia and Operation on the Kidney Function as Shown by the Phenolsulphonephthalein Test Arch Int Med March 1915 p 369

Occasionally, however, there is a temporary increase in postoperative phenolsulphonephthalein excretion In the consideration of the effect of gas oxygen anesthesia on the phenolsulphonephthalein excretion, Miller and Cabot say, "It would seem natural to expect the kidneys to show little or no effect after this anesthesia, whereas our few cases (nine) show even more decrease in output than after ether" It is worthy of note that this statement is confirmed by the results of the small series reported here, in which the increase in blood urea concentration following operation under gas-oxygen-ether anesthesia was slightly greater than the increase following similar operations under ether

Opportunity has recently been afforded to investigate changes in blood urea following major operations performed under local anesthesia It is suggestive that in three consecutive cases operated on under local anesthesia there was no postoperative rise in blood urea

BLOOD UREA DETERMINATIONS IN CASES OF UREMIA

In the series of patients examined, only six showed definite symptoms of uremia The blood urea findings are given in Table 5

TABLE 5—BLOOD UREA FINDINGS IN CASES OF UREMIA

Case No	Blood Urea at Different Stages	Results

2	181, 227, 262, 300, 413	Died
3	350, 400, 460	Died
4	146, 255, 293, 104	Improved
5	205, 200, 158	Improved
6	198, 115, 44	Improved

The patients in Cases 2, 4 and 6 were operated on, operations on the other three were not advised The first figures given are the blood urea values at the onset of definite uremic symptoms, except in the patient in Case 3 who was uremic on admission The patient in Case 1 had an extensive vesical carcinoma, and developed suddenly an almost complete anuria, possibly from occlusion of the ureters Case 2 was the emergency suprapubic cystostomy case mentioned before Case 3 was in a patient with marked arteriosclerosis and urinary obstruction due to prostatic hypertrophy The patient in Case 4 had a functionless left kidney, and a ureterolithotomy on the right side was necessary This was followed by a temporary occlusion of the ureter with development of uremic symptoms The obstruction disappeared and the patient improved rapidly after having had a maximum blood urea of 293 This is the highest blood urea with subsequent recovery encountered in this work Case 5 was in a patient with prostatic hypertrophy and urinary obstruction Case 6 was a prostatectomy case in which the patient developed a marked nitrogen retention, but with recovery The parallelism between the clinical picture and the blood urea findings in all these patients was very striking Foster[4] emphasizes the possibility of failing to recognize uremic states in patients with only a slightly increased nonprotein nitrogen, and believes that uremia in such persons occurs more frequently than is generally supposed In all the cases of uremia met with here, there was a very marked increase in blood urea

CLINICAL SIGNIFICANCE OF PHENOLSULPHONEPHTHALEIN AND BLOOD UREA TESTS IN SURGERY

In the consideration of the value and application of these tests one may assume that a high phenolsulphonephthalein output is practically always associated with a normal blood urea concentration and indicates that the patient has no renal lesion of sufficient importance to contraindicate operation under general anesthesia Of course, a routine urinalysis should always be made The rare cases of nephritis with superpermeability may be encountered On the other hand, a low phenolsulphonephthalein output does not necessarily contraindicate operation, for patients with a low phenolsulphonephthalein output but who have a normal or only slightly increased blood urea concentration often withstand an anesthetic and operation very well, other conditions being normal A low phenolsulphonephthalein output with a high blood urea concentration, however, does contraindicate an operation under a general anesthetic Of course, no absolute line can be drawn, but it is just this class of cases which show a marked increase in nitrogen retention after operation It is to be noted that often a thorough physical examination and urinalysis by themselves will fail to distinguish these cases

Blood urea tests are of especial importance in following a certain class of cases after operation, namely, those patients whose operations are such that extra-urethral drainage at various points of the urinary tract must be provided In such cases it is generally impossible to obtain a twenty-four hour specimen of urine, single specimens are often contaminated by discharges from the operative incisions, and it is impossible to do a phenolsulphonephthalein test because the specimens cannot be collected accurately In such cases blood urea tests are of very great importance as indicators of renal efficiency, and not infrequently it becomes advisable to operate on a patient who already has a ureteral, vesical or urethral fistula In these cases, as a rule, the blood urea or nonprotein nitrogen determination is the best indicator of the renal condition

SUMMARY

The agreement between phenolsulphonephthalein and blood urea tests is, as a rule, very striking, though not infrequently a low phenolsulphonephthalein excretion is associated with a normal or only moderately increased blood urea concentration

These tests are of great importance in selecting the most opportune time for operation so far as renal function is concerned

Following an operation under a general anesthetic there is, as a rule, an increase in blood urea concentration This increase is most marked after operations on the urinary tract and especially on patients who already have diminished renal function In a small series of cases this increase was slightly more marked following operations under gas-oxygen-ether anesthesia than following similar operations under ether

Blood urea determinations are of great value in the diagnosis and prognosis of uremic states Not infrequently blood urea concentration can be determined when other renal function tests are very difficult or impossible

In this investigation definite symptoms of uremia in uncomplicated cases appeared when the blood urea concentration reached 180 to 200

There is a definite group of patients who have a low phenolsulphonephthalein excretion but a normal or approximately normal blood urea concentration Many members of this group withstand a general anesthetic without any complications due to renal insufficiency

PARALYSIS DURING PASTEUR ANTIRABIC TREATMENT

WITH REPORTS OF SEVEN PERSONAL CASES, ONE TERMINATING FATALLY, AND SIX OTHER PREVIOUSLY UNREPORTED CASES *

FRANK S FIELDER, M D
NEW YORK

In the vast majority of instances, the Pasteur antirabic treatment is neither accompanied nor followed by any complications of importance The slight pain of the injections, some degree of local or constitutional reaction, occasionally a fairly marked urticaria, and possibly a localized abscess, if the physician is careless in the care of his syringe, are all the discomforts that are likely to be encountered

There is one rare complication, however, the so-called "treatment paralysis," which has long engaged the attention of those in charge of antirabic institutes, and the true nature and cause of which are not fully understood

This complication occurs with great rarity, and usually terminates in recovery, so that it should be considered no bar to antirabic treatment when this is evidently needed, but the possibility of paralysis should always be explained to those in whom infection is doubtful, or who are inclined to insist on being treated merely as a sentimental matter of precaution

The symptoms vary all the way from a slight degree of neuritis, with little or no motor involvement, to an acute ascending paralysis which may be fatal

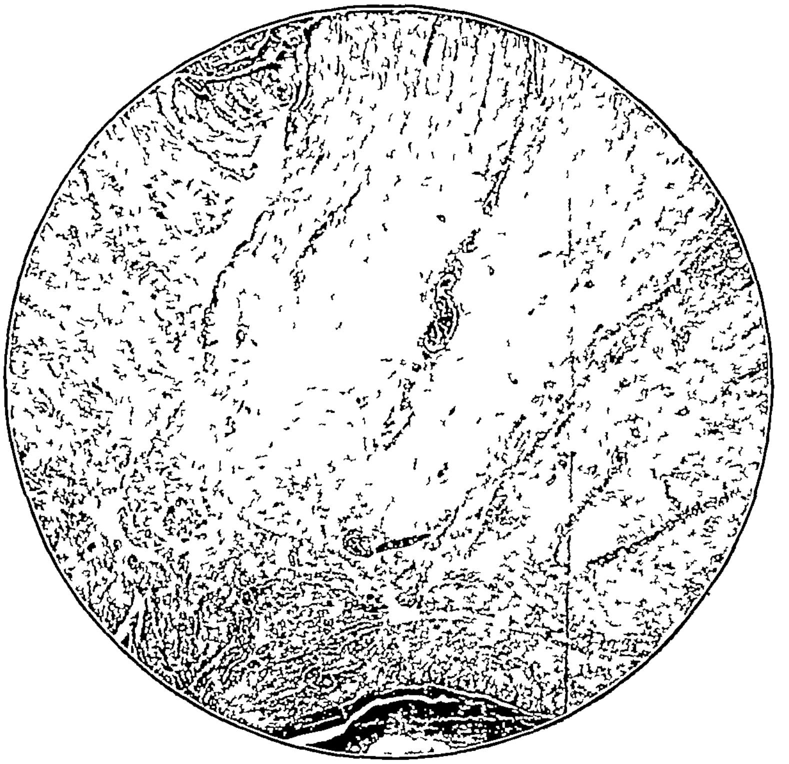

Fig 1 (Case 6)—Spinal cord cervical cord, considerably crushed showing dark streaks of fresh softening which follow in a general way the lines of the connective tissue septa right lateral column (of the illustration) more swollen than the left

An analysis of the parts of the body involved in thirty-seven of forty cases reported by Remlinger[1] in 1905 is as follows legs and sphincters, 17 cases, legs alone, 6, legs, sphincter, arms, face, 4, legs, sphincters, face, 4, arms and face, 1, arms alone, 1, face alone, 1, legs, arms, sphincters and bulbar symptoms, 1, legs and face, 1, and legs, sphincters and bulbar symptoms, 1 case Thus, in 37 cases, the legs were involved in 34, sphincters in 27, face in 10 and arms in 7 of the cases, while bulbar symptoms were present in only 2

The frequency of paralysis as a complication of antirabic treatment is variously estimated by different writers, but its real frequency is unknown, since many cases, especially the mild ones, are doubtless not reported

Remlinger,[1] in 1905, collected 40 instances of paralysis out of 107,712 patients treated, 2 of these being fatal Stimson,[2] in 1910, stated that later reports had brought the total up to 76 cases, with 4 deaths Simon,[3] in 1913, collected data up to and including 1911, showing the occurrence of 100 cases among 217,774 persons treated, and mentioned 3 other cases, without indicating the number treated In this series there were 19 deaths The incidence of paralysis, however, is evidently different under different methods of antirabic treatment Simon's[3] figures showed 6 cases among 32,676 patients treated by the classical Pasteur method 16 cases among 8,659 patients treated by the modified (more intensive) Pasteur method, and only 3 cases among 51,417 patients treated by the Hogyes method, with dilutions of fresh fixed virus

Hasseltine,[4] in a brief review of the literature since Simon's report, mentions cases reported, by Higier,[5] Hudovernig,[6] Sterling,[7] Kozewalow,[8] Mucharinski, Abramov, Jochmann,[9] Goldberg and Oszesalski,[10] and Fabricius[11] Hasseltine adds four cases of his own, one of which was fatal, and states that he has knowledge of two other cases, reports of which are as yet unpublished He quotes Park and Williams,[12] who state that there have been seven cases of paralysis with two deaths among 6,850 cases treated by the Pasteur clinic of New York City health department, including the year 1913 Hasseltine thus brings the total to 133 cases, up to and including 1913, with twenty-five deaths

Poor,[13] in 1909, re-

[13] Poor D W An Occasional Complication of Pasteur Antirabic Treatment Col Studies Research Lab Dept of Health New York City 1908-1909 p 121

ported eight cases of neuritis without paralysis, and four of paralysis, one of which was fatal, among 2,300 patients treated by him at the New York City health department The figures of Park and Williams, quoted above, include Poor's four cases of paralysis, and three of the cases, including the fatal one, which are reported in the present paper

My seven personal cases, together with the six other cases which are here first reported, thus bring the total up to 143 cases with twenty-five deaths This should be corrected to 142 cases with twenty-four deaths, since Poor's fatal case and that of Fabricius were the same

The mortality among these published case reports, 16 2 per cent, must not be taken as representing the true mortality incident to this complication of antirabic treatment, since it is certain that many mild cases are not reported, while it is likely that reports of most of the severe and fatal ones have been published Although the average mortality among published reports of paralysis is from 15 to 20 per cent, this is reduced to a negligible figure when compared with the total number of cases treated Simon's[3] figures, 100 reported cases with nineteen deaths among 217,774 patients treated at various institutes, show a mortality of 19 per cent among the patients developing paralysis, but so rarely does a case occur that the incidence of the disease in his series was only 0 048 per cent and the mortality but 0 00812 per cent of the total number of cases treated

As regards prognosis, the cases may be roughly divided into three classes The mild ones with transitory paralysis of face or limbs all recover The acute paraplegias of the lower extremities with or without the involvement of the sphincters usually recover Death, if it occurs, is likely to be due to cystitis or bedsores after a prolonged illness Remlinger[1] reported two deaths in forty cases, and Simon[3] three deaths in twenty-four cases of this type The severest cases presenting the clinical picture of an acute ascending paralysis of the Landry type have a bad prognosis Simon reported fifteen deaths among thirty-six such cases, a mortality of 41 6 per cent The deaths in this group occur in a few days from respiratory or cardiac paraysis, or later, from inhalation pneumonia, cystitis or bedsores

The time of development of symptoms is fairly characteristic According to Simon,[3] they usually make their appearance from eleven to thirty days after the bite, and between ten and twenty days after the beginning of the injections Only one quarter of the cases develop after the completion of a full course of treatment, and most of these within seven days thereafter

In the thirteen cases reported in the present paper, the development of first symptoms of paralysis in relation to the date of the bite, and to the beginning of treatment, is as follows My seven personal cases Symptoms first appeared during treatment in six cases, and three days after its completion in one case Average, twenty-three days after the bite and seventeen days from beginning of treatment Among the six other cases, symptoms first appeared during treatment in four cases In two cases they appeared two and ten days, respectively, after treatment Average, twenty-six days after the bite and seventeen days from the beginning of treatment

These figures tend to bear out Simon's statement that whether counting from the date of the bite or from the beginning of treatment, the incubation is shorter than in most cases of rabies This fact is important in view of the contention of some writers that the condition is one of true rabies caused by the bite, but rendered mild by the antirabic treatment

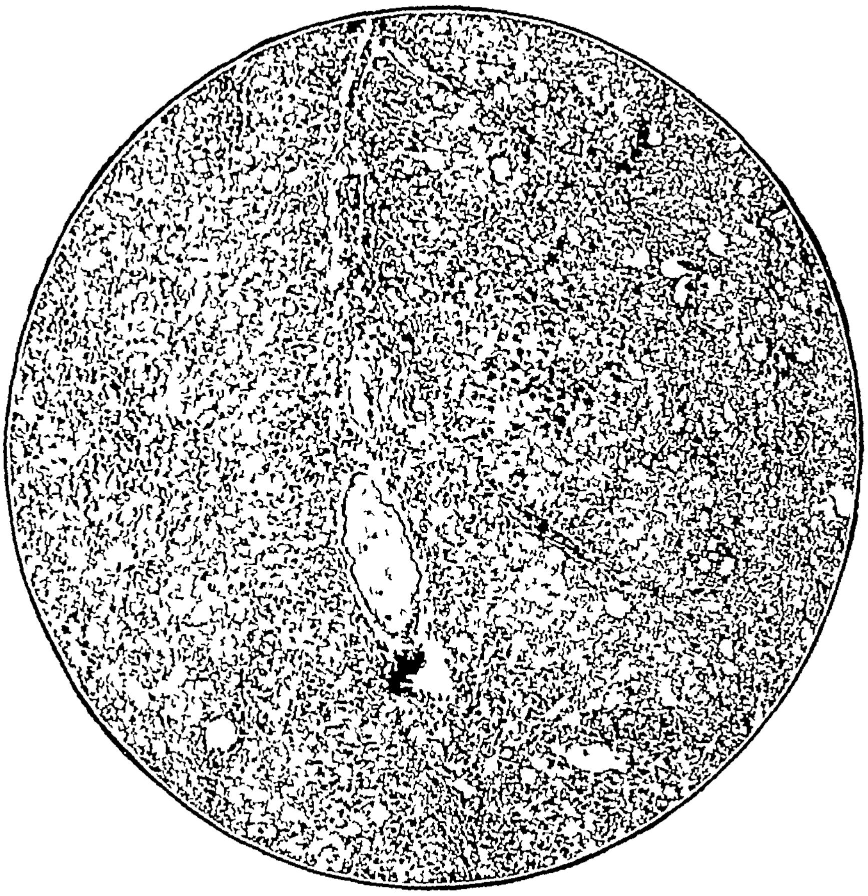

Fig 2 (Case 6) —Spinal cord acute softening, showing as darker staining polycellular strips on either side of the connective tissue septa, the rest of the section, except for numerous small holes, looks practically normal, and shows plain axis cylinders surrounded by their sheaths

The onset of the symptoms is usually acute, with pain and numbness of the affected parts, followed by muscular weakness Prodromal symptoms if present are mild, and consist only of malaise and nervous depression, with perhaps some restlessness, insomnia and anorexia

Males seem to be affected much more frequently than females In Simon's[3] publication, among 84 cases there were 60 males and 10 females, 6 of the remaining 14 were unknown Hasseltine's[14] 4 cases were all in males Of my 7 personal cases, 5 were male, and of the 6 additional cases reported, all were male This preponderance of males is probably partly due to the fact that undoubtedly more males are bitten and thus more are treated Unfortunately, available statistics do not state the relative proportion of males and females in the total number of cases treated

Young children are rarely affected Most of the cases occur in adults of varying ages All of the thirteen cases reported in this paper were in adults between 23 and 62 years of age, the average being 41 years Seven of the patients were in the thirties

It is stated that persons who are alcoholic, syphilitic or neurotic are more likely to be affected than those who have no such taint, but exceptions to this rule occur fairly often Paralysis occurs so rarely in proportion to the total number of cases treated that a special idiosyncrasy on the part of the patient must be assumed

[14] Hasseltine H E Paralysis During Antirabic Treatment, Pub Health Rept, Oct 24, 1913, p 2220, ibid, July 30, 1915, p 2226

PATHOLOGY

Jochmann[9] in a careful study of a fatal case, found the lesions disseminated, but especially localized in the lumbar and cervical cord, and associated with a perivascular serous transudation and with marked edema of the meninges of the dorsal and lumbar cord Small foci of softening were present in the lumbar cord The large ganglion cells of the gray matter had partly disappeared, some were atrophied and their chromatin had gone into solution A mild round cell infiltration was noticeable throughout the whole cross-section of the gray matter The same changes were found in the cervical cord, but to a much less degree The brain findings were not described, except that Negri bodies were not demonstrated Rabbits, rats and dogs were inoculated by Joseph Koch from the lumbar cord in this case Some of the animals, after a long incubation, died of rabies In two of the rabbits, Negri bodies were found in size and shape as they occur in inoculation rabies

The serous exudation and meningeal edema which occurred in the lumbar cord in this case would explain the otherwise puzzling clinical fact that in spite of a most severe syndrome, such as complete flaccid paralysis of the extremities, colon, bladder, etc, the symptoms may begin to abate within a few days, and a rapid cure result

ETIOLOGY

The etiology must still be considered as not definitely settled The principal explanations advanced for the phenomena observed are

1 *Anaphylaxis,* due to repeated injections of foreign protein as contained in the rabbit cord employed This explanation was advanced by Harvey and McKendrick,[15] and entertained by Muller[16] It is conceded that the Hogyes method of treatment with diluted fresh fixed virus, in which the proportion of nerve substance is at a minimum, is far less often complicated with paralysis than is the Pasteur method in which the amount of nerve tissue is much larger The summary from Simon[8] (Table 1) shows this

TABLE 1—INCIDENCE OF PARALYSIS UNDER DIFFERENT METHODS OF ANTIRABIC TREATMENT

Method	Number of Cases Treated	Cases of Paralysis	Proportion
Classical Pasteur method	32 676	6	1 5446
Modified Pasteur method	8 657	16	1 541
Högyes method	51 417	3	1 17130

If the foreign protein material in itself were the cause of "treatment paralysis," the percentage of cases occurring under the classical and modified Pasteur methods should be approximately the same, since they contain about the same amount of nerve substance, differing only in the strength of material used Yet, as shown by Table 1, paralysis occurs ten times as often under the modified (intensive) as under the classical Pasteur method

Another point against the anaphylaxis theory is the fact that paralysis has not been produced in animals by the injection of large amounts of normal nerve tissue

2 *The specific action of a "rabies toxin"* which is in combination with the fixed virus used for treatment Remlinger[1] and Babes[17] have held that this, together with an idiosyncrasy on the part of the patient, is responsible for the symptoms Babes showed that animals injected with fixed virus which has been filtered or otherwise treated so as to eliminate infection by a micro-organism do not die of rabies, but develop fever, emaciation, cachexia and paralysis, and die after a protracted period The theory of a toxin is a plausible one, but there is no agreement in regard to it

3 *Street virus infection,* received from the biting animal, and so modified by treatment that the disease runs an atypical and usually mild course ending in recovery

This view was held by Joseph Koch[18] He inoculated animals from the lumbar cord in a fatal case Some of these, after a long incubation, died of rabies He explained the negative results obtained by Babes in four cases by the fact that Babes had used only the brain and medulla for inoculation, whereas it is the cord in these patients that is infective

More lately Jochmann[9] has defended the same view and has attempted to explain in accordance with this theory the cases such as Franca's[10] case quoted below, which seem to others to disprove it

Against this view are the following facts A number of cases have occurred in which the biting animal was not mad, and others in which the patients were not bitten, but had taken antirabic treatment merely as a precaution Pain at the site of injury is rarely felt in paralysis cases The incubation period is usually too short for infection with street virus Paralytic rabies in animals is regarded as an intense rather than an attenuated form of the disease, therefore street virus rabies, modified by treatment so as to become mild, should not be of the paralytic type

4 *Fixed virus infection due to the treatment* It is held by some writers that the unusually early appearance of symptoms in occasional cases is against this view Strong emulsions are not commonly injected during the first days of treatment, yet the paralytic symptoms sometimes appear within seven days after the first injection of strong cord material They also insist that if fixed virus possessed virulence for man, paralysis would be of frequent occurrence among the thousands of persons treated every year, whereas it is well known that it is very rarely seen

Among others, Kozewalow[8] holds that fixed virus infection is responsible for most instances of paralysis incident to antirabic treatment In defense of his position he cites several fatal cases with necropsies followed by animal inoculations

(*a*) A case of his own with symptoms of ascending paralysis No Negri bodies were found in the patient s brain Animal tests comprised thirty-three rabbits inoculated with the brain material Twenty-four of these died of rabies with an *incubation of from* six to seven days The others died of sepsis

[19] Franca Du danger de l emploi des moelles plus virulentes dans le traitement de la rage Centralbl f Bakteriol Abt I Orig 1910 lv 154

(*b*) Five cases from Bareggi[20] following treatment with fresh fixed virus The patients died within a week of acute ascending paralysis Rabbits inoculated from their brains showed symptoms of rabies in from five to six days

(*c*) Franca's[19] patient, bitten by a dog not rabid (microscopic and inoculation tests negative) Patient developed ascending paralysis on the fifteenth day of treatment She had received a one-day cord injection for the first time three days previously On the sixth and eighth days of illness spinal fluid was withdrawn and injected into the anterior ocular chamber of three rabbits After eleven days one of these died with symptoms of rabies Two other rabbits were inoculated subdurally with the cord of this rabbit Both developed rabies on the seventh day, and died on the ninth day after vaccination A rabbit injected intramuscularly with the cord of this rabbit died nine days later with typical symptoms of rabies The patient died on the fortieth day of illness It is said that this case has modified Koch's view so that he has admitted the possibility of fixed virus as well as street virus infection in these cases

(*d*) The case of Goldberg and Oszesalski[10] a boy of 13 years bitten by an unknown dog which was not captured He received six injections in the next four days in a Warsaw institute He then stopped treatment and walked 200 kilometers to his home Thirteen days after the bite and twelve days after the first injection, he was taken sick with symptoms resembling cerebrospinal meningitis The cerebrospinal fluid, however was negative bacteriologically and consciousness was retained throughout The boy died suddenly from respiratory paralysis after five days No Negri bodies were found The emulsified spinal cord produced rabies in rabbits in from seven to eight days

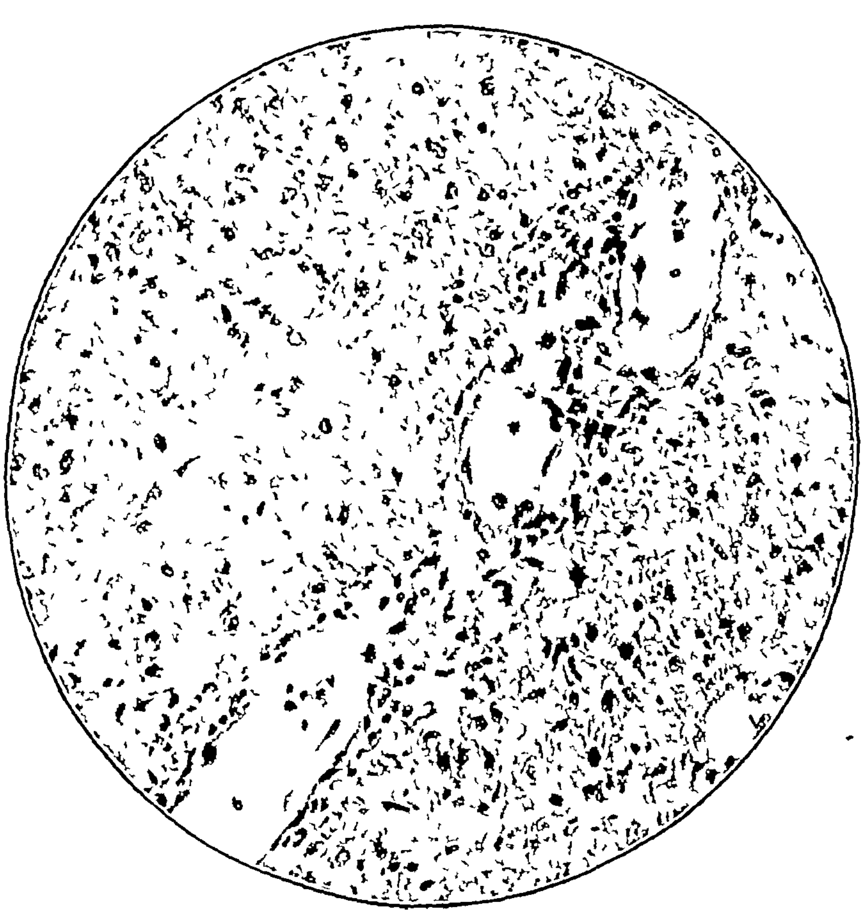

Fig 3 (Case 6) —Spinal cord a softened area, more highly magnified than in Figure 2, showing, very poorly, the Gitter or granule cells these are best seen perhaps in the right lower quadrant in the left upper corner of the illustration, axis cylinders and myelin sheaths which still retain their form may be seen, note lymphoid cells in the sheaths of the blood vessels

Kozewalow[8] holds that the short incubation of rabies in the animals inoculated from these cases demonstrates that these paralyses are directly due to fixed virus infection As further proof of his position, he states the following facts At the beginning of 1909 the treatment in Cracow was intensified, and the use of a one-day cord begun, whereas, before that, nothing stronger than a two-day cord was used Shortly afterward they began to have cases of paralysis Not less than twenty persons were affected in the course of a month The symptoms were mild, and consisted of paresis of the arm or leg, or partial urine retention, and passed off in one or two days The use of the one-day cord was then discontinued, and the symptoms stopped He cites experiments of Kraus and Fukuhara,[21] who proved that different strains of fixed virus in different institutes vary in virulence, since some are virulent subcutaneously in rabbits and white mice, while others are nonvirulent He gives the results of some experiments of his own, and states that each institute should analyze its own virus and determine whether it can or cannot use an intensive treatment

In connection with these statements of Kozewalow, the experiences of Poor[13] and of myself are very suggestive Of Poor s twelve cases, one occurred in 1906, four in 1907, and seven during the nine months between February and October, 1908, after which, up to the time of his report, nine months later, no more cases had occurred About October, 1908, he began to inoculate rabbits from the cord rather than from the brain of the rabbit of the preceding series Thus he undoubtedly used a weaker virus, as the rabbits did not show initial symptoms until a day, sometimes two days later than by the other method He also gave smaller and weaker doses to those who were but slightly bitten

I have used three different schemata of Pasteur treatment, the full course in each being twenty-one days

Table 2 will show their comparative strength by indicating the number of injections of each cord in a full course of twenty-one days' treatment It also shows the number of cases of paralysis and of rabies which occurred among the patients treated under each scheme

Thus it will be seen that Scheme 2 is somewhat stronger than Scheme 1, since it contains three more injections of two-day cord, and much stronger than Scheme 3, which includes nothing more active than three-day cords Scheme 2 is very similar to the one employed by the Hygienic Laboratory of the U S Public Health Service, Washington, D C, and by most of those who produce antirabic vaccine in this country, with the following differences 1 The amount of cord per dose was only two thirds as much as that employed in the Washington scheme 2 We used a two-day cord instead of one-day cord on the eighth and twenty-first days of treatment

One of my cases of paralysis, Case 1, occurred in 1912 while Scheme 1 was in use Other cases may have occurred under this plan previous to 1912, but the records were not available for examination

Five of the remaining six cases, including the one terminating fatally, occurred between Aug 15 and Oct 17, 1913, in the early weeks of the employment of Scheme 2 Although the plan was not changed, another case did not develop until the following spring Strangely enough, in November and December, 1913, the rabbits used for producing the antirabic vaccine showed a tendency to develop initial symptoms in five or even four, instead of six days and it was necessary to use lumbar cord and sometimes cord dried one day, instead of medulla, for inoculation, in order to bring the incubation back to six days Still no paralysis cases occurred during this period Finally, May 1, 1914, at a time when the rabbits were coming down in exactly six days another case of paralysis developed (Case 7, a severe one, with recovery)

TABLE 2—SCHEMES OF PASTEUR TREATMENT USED BY NEW YORK CITY HEALTH DEPARTMENT

Cord Dried	Scheme 1	Scheme 2	Scheme 3
	Jan 1 191 to Aug 2 1913	Aug 3 1913 to May 6 1914	May 7 1914 to Mar 7 1916
	Number of injections in 21 days	Number of injections in 21 days	Number of injections in 21 days
Ten days	3	0	0
Nine days	3	0	0
Eight days	1	1	2
Seven days	1	1	2
Six days	1	1	2
Five days	1	2	2
Four days	3	5	6
Three days	3	7	8
Two days	3	8	0
No of patients treated	1 405	811	911
Cases of paralysis	1	6 (one fatal)	0
Cases of rabies	4	2	4

Scheme 3 was then adopted In this no two-day cords are used except occasionally in a case of very severe face bite Since then no instances of paralysis have occurred (from May 7, 1914, to March 7, 1916, a period of twenty-two months)

In my one fatal case of paralysis, the brain and cord were unfortunately put into liquor formaldehydi, so that no opportunity of trying animal inoculation was afforded I therefore can express no opinion, based on experience, on the important question whether or not these paralyses are due to fixed virus infection However, there is no doubt in my mind that in most of the cases, at least, the symptoms are caused, not by street virus infection, modified by the treatment, but by the treatment itself either through the medium of fixed virus infection or through the action of a toxin, or both In any event there must be a special idiosyncrasy on the part of the patient Otherwise the cases would be enormously more frequent than they are

Table 3 shows, as in Simon's series,[8] that the lower extremities, sphincters and face are most often involved, in the order named

TREATMENT

The treatment of these patients is to be conducted on general principles, according to the parts of the body involved No special type of treatment based on the peculiar etiology of the condition has been developed

If the patient has been bitten by a dog known to have been rabid, the preventive inoculation should not be discontinued, since in numerous reported cases they have been persisted in without apparent detriment They may be discontinued if the biting animal was probably not rabid

CONCLUSIONS

1 Paralysis complicating the Pasteur antirabic treatment is very rare, but doubtless occurs in mild form more often than is known It affects adults chiefly, young children almost never

2 The prognosis is good in cases of mild or moderate degree, but the mortality among the severe cases is high

3 The administration of antirabic treatment is therefore not entirely devoid of risk

4 The possibility of the occurrence of paralysis in any particular case, however, is so slight that it should not deter those who evidently need antirabic treatment A person bitten by a rabid animal is much more likely to develop rabies, which is certainly fatal, than paralysis, which usually ends in recovery

5 The slight risk of paralysis should always be explained to those who are inclined to insist on antirabic treatment in the absence of clinical or laboratory evidence that the biting animal was rabid

6 In most instances this paralysis is caused by the antirabic treatment itself (fixed virus infection, or toxin, or both) It is not often due to street virus

TABLE 3—BRIEF SUMMARY OF CASES FIRST REPORTED IN THIS PAPER

	Case No	Symptoms Began		Parts of Body Involved	Improvement Began After	Termination
		Days After Bite	Days After Beginning of Treatment			
Author s Personal Cases	1	23	19	Both legs below knees	Few days	Recovery after a few weeks
	2	14	13	Lower extremities and bladder	Few days	Recovery after a few weeks
	3	17	15	Upper and lower extremities trunk throat	Few days	Recovery after a few weeks
	4	53	18	Face both sides	Few days	Recovery after a few weeks
	5	17	13	Both legs below knees	Two days	Recovery after a few days
	6	14	13	Lower extremities abdominal muscles intestines and sphincters completely paralyzed Upper extremities weak	No	Died after 11 days*
	7	20	15	Lower extremities and sphincters completely paralyzed	After 2 weeks	Recovery practically complete after 6 months
Additional Cases	8	54	23	Face right side	?	Recovery after 4 weeks
	9	14	12	Lower extremities and sphincters	After 9 days	Recovery complete after a few months
	10	53	31	Face right side	Few days	Recovery after 2 weeks
	11	20	16	Face (slight) legs weak	?	Recovery gradual complete after 6 months
	12	19	14	Left leg and bladder	?	Poor condition after 10 days no further report
	13	16	12	Legs and bladder	?	Symptoms persisted after 8 days no further report

---

* Necropsy showed spinal pachymeningitis macroscopically No inoculation tests as brain and cord were put into liquor formaldehydi by mistake Stained sections of hardened brain showed no Negri bodies and no special lesions Cord showed acute softening most marked in cervical well marked in dorsal and less marked in lumbar region

infection modified by the treatment Its incubation is shorter than that of most cases of street virus rabies

7 Variations in the strength of the fixed virus used are probably a factor in the etiology

8 Personal idiosyncrasy is an important predisposing condition

CONGENITAL STENOSIS OF THE DUODENUM IN AN ADULT*

WALLACE I TERRY, M D
SAN FRANCISCO
AND
ALSON R KILGORE, M D
SHANGHAI, CHINA

Congenital stenosis of the duodenum is an uncommon condition, almost always fatal in early life The reported cases, collected in several careful reviews, have all been in infants dying under 6 months No new review will be attempted here, except briefly to summarize the conditions described Louise Cordes[1] found fifty-seven cases reported to 1901 — forty-eight of complete atresia fatal in less than nine days, and nine cases of stenosis without complete blocking, the longest duration of life in which was 6 months

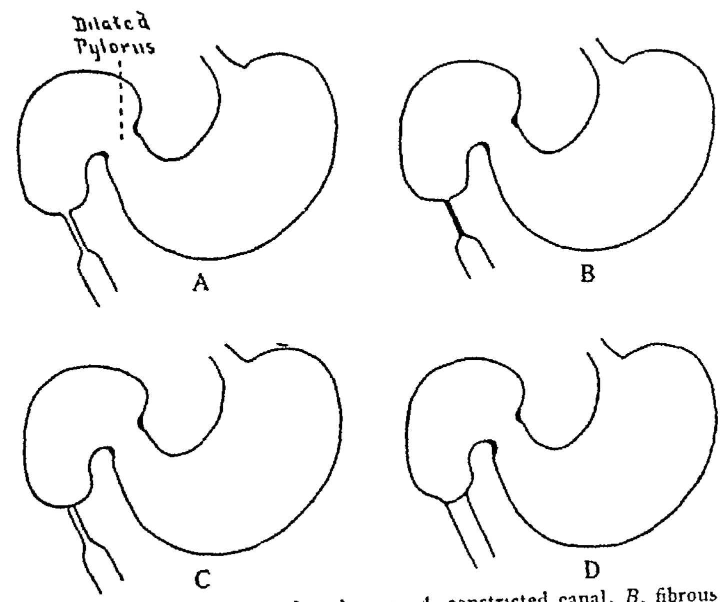

Fig 1 —Various forms of occlusion *A* constricted canal, *B*, fibrous cord, *C* blind pouch *D*, transverse membrane

The literature later has been reviewed by Meusberger[2] and Weber,[3] who found that to 1910 there had been reported between sixty and seventy cases of congenital duodenal stenosis, this number representing from one fourth to one third of the total number of cases involving all parts of the small intestine — about 200 Since 1910, several additional cases have been reported by Roe and Shaw,[4] Gray,[5] Weber[6] (who operated in his case but without success), Hauser,[7] McDonald,[8] White,[9] and others, bringing the total number up to about seventy-five

In all of the cases reported in the reviews mentioned and in the cases which we have found reported since, the condition has been fatal in from a few days to a few months at the longest [10] Kermauner[11] states that congenital stenosis of the duodenum may be of such mild grade that it is not discovered until later in life, but he cites no cases The case we have to report, therefore, is unlike any that we have been able to find described

VARIETIES OF STENOSIS

The occlusion may take any one of varied forms, but most of the cases can be grouped according to a few common types as follows

1 There is a constricted canal, lined with fairly normal intestinal mucosa (Fig 1 *A*) The occlusion is incomplete

2 A fibrous cord represents the constricted intestine It may be 1 or 2 cm in length, or may extend from the pylorus to the papilla of Vater (Fig 1 *B*)

3 The duodenum may end as a blind pouch, and the intestine begin again with a constricted lumen from the tip of this pouch, like an appendix springing from the cecum (Fig 1 *C*) Such a case is reported by Roe and Shaw [4]

4 Two cases have been reported of occlusion by a comparatively thin transverse membrane[12] (Fig 1 *D*), in one of these,[13] there were found smooth muscle fibers between the layers of epithelium, indicating the structure of actual intestinal wall in the membrane

5 The relation of the occlusion to the common duct is of interest Most of the obstructions occur in its immediate neighborhood, either above or below the papilla, though they may occur in any portion of the duodenum In four cases of partial occlusion,[1] the common duct opened into the stenosed portion Cordes also reported a case in which the blind pouch of duodenum was connected with the papilla of Vater by a small canal having the microscopic characteristics of the gallduct She found two or three similar cases reported, and considered that in several other instances such a connection must be assumed to explain the vomiting of bile-stained material in cases in which the duodenal occlusion was above the papilla No satisfactory embryologic explanation of this curious anomaly of the gallduct has been offered

The possible causes of congenital stenosis of the duodenum suggested in the literature were (1) errors of embryologic development of the duodenum, (2) volvulus in fetal life, (3) fetal peritonitis (usually tuberculous or syphilitic), (4) ulceration, (5) pressure from new growths, (6) abnormal persistence of the omphalomesenteric duct, (7) traction on the intestine, due to hernia, (8) circulatory anomalies (absence of arterial branches), (9) embolism of the superior mesenteric artery, and (10) pressure from an enlarged head of the pancreas

In forty-nine of the fifty-seven cases, no evident cause could be found except faulty development of the duodenum itself That this is the usual cause is also suggested by the most common location of the constriction, near the orifice of the common duct, that is, at about the junction of the embryonic foregut and midgut, and at a point where very active embryologic processes take place — the development of the liver and pancreas — and where other congenital anomalies (diverticula) are prone to occur Furthermore, atresia of the duodenum is frequently associated with other defects which are clearly developmental The developmental origin is also indicated by the work of Tandler and later by Forssner,[14] who found that the second portion of the duodenum, which is at first open during the latter part of the first month of embryonic life, becomes occluded by proliferation of its own epithelium, and remains so during nearly the whole of the second month It is suggested that a failure in the absorption of this occluding plug of epithelium is responsible for some of the atresias found at birth

[10] Ochsner (Ann Surg, 1906, xliii, 80) has reported a condition of thickening of the circular muscle fibers of the duodenum, which he considers to be the cause of symptoms in adult life But this condition, he stated, was constantly found below the papilla of Vater, thus differing from true congenital stenosis, which occurs with equal frequency above and below the common duct Boothby (Boston Med and Surg Jour, July 18, 1907) was unable to confirm Ochsner's findings.

[12] Weber (Footnote 3) Keith Brit Med Jour, Feb 5, 1910 p 301

[13] Keith (Footnote 12)

The only constant symptoms of the condition are persistent vomiting of everything ingested, beginning at birth, with emaciation and death in a few days (the symptoms being somewhat modified, of course, in the few cases of incomplete obstruction) Cases in which the obstruction was below the orifice of the common bileduct have been diagnosed during life by the passage of white meconium and the vomiting of bile-stained material

The treatment is, of course, only operative, but so far has not had success Braun[15] in 1902 collected from the literature the reports of twenty-five operations for congenital intestinal stenosis of all parts of the small intestine — enterostomies, gastro-enterostomies, and entero-anastomoses—with a mortality of 100 per cent

CASE REPORT

History —F S (U C Hospital No 8686), man aged 24, American, transferred from the medical service' of Dr H C Moffitt, presented essentially negative family and past history and habits His illness began twelve years ago at the age of 12, with a year of intermittent, rather indefinite pain in the lower abdomen, followed by three and a half years of freedom, and then four years more of similar attacks at intervals of from three to four weeks The pain was always below the umbilicus extending 5 cm to either side of the midline without radiation There was no definite relation to food It was relieved by hot drinks and occasionally by defecation It was usually worse at night

He had had no definite pain for five years, but four years ago vomiting had begun, and had grown progressively worse, usually coming after the evening meal, sometimes after other meals There had never been hematemesis or melena During this four years there had been progressively increasing weakness, with dizziness, etc His appetite had been good, but he had limited his diet through fear of vomiting finding that liquid food gave him least trouble He had lost 15 kg in the past seven years 6 kg of this during the past six months He now weighed 51 kg (112 pounds)

Physical Examination —This showed much emaciation The abdomen was scaphoid except for a prominence about the umbilicus (distended stomach), over which there was marked peristalsis from left to right The lower border of the stomach was seen and percussed midway between the umbilicus and the symphysis Liver, spleen and kidneys were not felt The reflexes were normal There was, however, a slight but definite Chvostek's sign No Trousseau's sign was made out Erb's was doubtful Physical examination otherwise was not remarkable

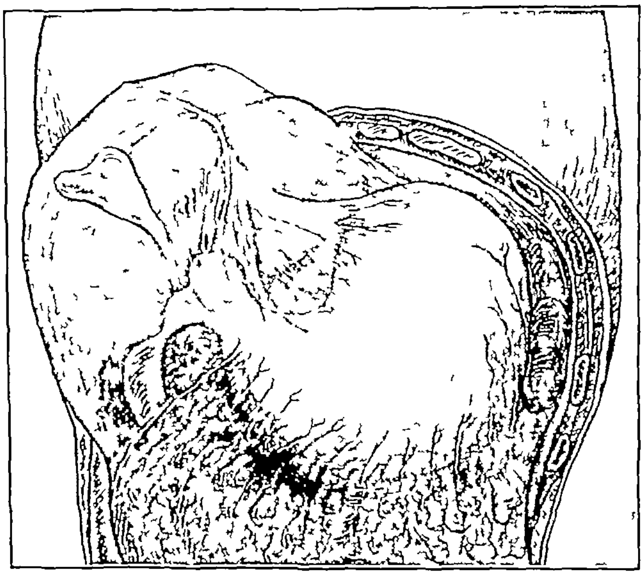

Fig 2 —Conditions found at operation (semidiagrammatic)

Wassermann test on blood serum was negative

Stomach wash, fasting, yielded 80 c c of reddish brown fluid, with free hydrochloric and lactic acid present but no occult blood Sarcinae were present in large numbers There were no Oppler-Boas bacilli

Ewald meal showed Free hydrochloric acid, 22, total acid, 42 (low normal)

Blood and urine were normal

Stool examination was negative to guaiac

Unfortunately a bismuth roentgenogram of the gastro-intestinal tract could not be obtained

A diagnosis of pyloric stenosis was made, thought to be due either to an old ulcer or to a congenital condition

Operation —The stomach was found to be much dilated and low in the abdomen There were some old adhesions across both the anterior and posterior aspects of the stomach toward the pyloric end, but none about the duodenum except two very thin strands between the pylorus and gallbladder The pyloric ring was much dilated The first portion of the duodenum was dilated, the upper wall forming a definite pouch Just distal to this dilated portion at about the junction of the first and second portions of the duodenum and above the entrance of the common duct, the intestine was evenly constricted to one third or less of its normal diameter for about 1 5 cm There was no thickening of the wall, and no scars could be found and no abnormalities of the peritoneum to account for the constriction

The gallbladder was free, not distended or thickened There was a slight constriction, causing a suggestion of sacculation of the outer third of the fundus (probably congenital)

The appendix was long atrophic and buried in old adhesions (probably the explanation of the patient's earlier attacks of pain)

A posterior gastro-enterostomy was done, and when the stomach was cut into marked thickening of the wall was noted in spite of the dilatation of the organ, indicating long-standing obstruction

The patient vomited during the first forty-eight hours following the operation, the vomitus containing considerable blood. Following this he was delirious much of the time, and on this account was given occasional nasal feedings On the fifth day he was apparently much improved and took considerable nourishment, but vomited small amounts twice during the afternoon Quite suddenly in the evening, the pulse rate increased and respirations became shallow and rapid, and he gradually sank into coma and died in six hours

Necropsy —The necropsy performed by Dr J V Cooke showed the conditions described at operation In addition there was marked dilatation of the stomach with partial breaking down of the gastro-enterostomy wound leakage of stomach contents into the peritoneal cavity, and beginning peritonitis

[14] Forssner quoted by Keith (Footnote 12) and also by Shaw and Baldauf Albany Medical Ann 1908 xxix 148

[15] Braun Beitr z Chir 1902, xxxiv 993

When preserved in liquor formaldehydi, the constriction of the duodenum presented the appearance of an obstructing fold of the duodenal wall rather than of a narrow tube, 15 mm. long, as it had appeared before fixation. Grossly and microscopically the constriction was covered with normal mucous membrane, and careful search failed to reveal any scar tissue or other evidence of old ulceration. The condition was therefore considered to be congenital in origin, the type of occlusion corresponding to that represented in Figure 1 *A*. The possibility of the condition being caused by an old ulcer which had disappeared without leaving any trace of itself was, of course, considered, but this is quite improbable, and is all the more unlikely in view of the rarity of duodenal ulcer in early youth.

In 302 cases of ulcer of the duodenum reported by Moynihan,[16] there were but three occurring under 20, his youngest patient being aged 17. In the case here reported, symptoms of stenosis had already developed by the age of 20.

Why symptoms due to congenital duodenal stenosis should appear only after several years of life and then grow progressively worse is difficult to understand. It is possible, however, that in the process of growth the constricted portion may not have increased in diameter in proportion to the rest of the duodenum, so that the *relative* degree of obstruction was increased. Then, too, as the obstruction began to affect the patient's nourishment, dilatation and ptosis of the stomach were undoubtedly increased and, in turn, tended to aggravate the stasis, thus producing a vicious cycle.

It is of interest to compare the history of this case with those of five cases reported by Harris[17] of constriction of the duodenum by what he considered to be a congenital fold of peritoneum derived from the lower border of the embryonic ventral mesogastrium. This fold extended from the gallbladder across to the mesocolon in such a way as to constrict the duodenum at the second portion. The duodenal wall itself was normal, the lumen of normal size, and the condition was relieved in each case by dividing the constricting fold. The histories of his cases were similar to that of our case — characterized by their chronicity, symptoms beginning in youth or early adult life and growing progressively worse, with periods of improvement but not of complete freedom from distress. They presented rather indefinite epigastric distress, often with a few attacks of quite sharp pain. They differed, however, from the case here reported in that vomiting was not a characteristic symptom. The point of interest is that, if Harris is right in considering the condition to be congenital, his cases show the possibility of congenital constrictions of the duodenum causing symptoms which do not begin until after several years of life.

SUMMARY

1. Congenital duodenal stenosis is a rare condition, almost invariably fatal in infancy.

2. A case is reported in an adult, characterized by a history beginning in adolescence before the usual ulcer age and growing progressively worse, the symptoms and findings indicating benign pyloric stenosis.

Influence of Digestion.—A light supper, a good night's sleep and a fine morning have often made a hero of the same man who, by indigestion, a restless night and a rainy morning would have proved a coward.—Chesterfield.

PNEUMOTHORAX OF UNCERTAIN ETIOLOGY *

ARTHUR H. TERRY, Jr., M.D.

NEW YORK

Pneumothorax is said to be spontaneous or natural when there is no evident external or internal cause. There must be a cause, but in many cases it is difficult to find and impossible to prove. The report of the following case very well illustrates these points.

History.—The patient is a man, aged 25, who has been under my observation for three years with several routine physical examinations. Nothing abnormal has been detected in heart or lungs. He was always considered a healthy, active young man. His father died of heart trouble several years ago; his mother is living and well. He has no brothers or sisters. There has been no tuberculosis or cancer in the family.

His habits are good. He has never had syphilis. He smokes a pipe four or five times daily and takes an occasional glass of beer. There has been no recent change in weight or mode of living. He has had a few colds lasting only a few days, and also some very slight digestive complaints. There is no history of infectious diseases. There has been no chronic cough, loss of weight, continued fever, night sweats or suspicion of tuberculosis. The patient complained one year ago of some pain and tenderness directly over the ensiform cartilage. This lasted three weeks unassociated with cough or fever, and was diagnosed as a strain.

Present Illness.—On the day previous to examination the patient took his usual cold shower, and without any unusual muscular or respiratory effort felt something "give way" or "grow loose" in his episternal region, inside of him. This gave him a queer indescribable sensation as of something having gone wrong. It caught him to draw a deep breath, and full inspiration was attended by a short, dry, expiratory cough. He went to bed directly, but had to lie perfectly quiet, any change in position being uncomfortable. If he attempted to rise it caught him in his back like a lumbago. He did not consider himself seriously ill, and did not feel sick, yet he believed that something had gone wrong inside of him. There was no dyspnea, nausea, chill, fever or sweat, and the patient was comfortable when quiet.

Physical Examination.—The temperature was 98.6, pulse, 80, respiration, 20. Inspection revealed a well developed young man, not sick and yet worried, somewhat pale and anxious. There was no dyspnea or cyanosis when he remained quiet, but rather marked dyspnea on the slightest exertion. The left chest was fuller than the right, the intercostal spaces bulging rather than concave, and no expansion. The right chest was normal in shape and respiratory excursion. There was no visible apex impulse to the left of the sternum but some cardiac impulse in the substernal notch. The apex impulse was not palpable. Fremitus was absent over the entire left chest, and normal over the right chest. There was no expansion of the left chest, and 1 inch expansion of the right chest. Percussion revealed a dull tympany from the apex to the base of the left chest, with no area of cardiac dulness. The right chest was normally resonant, with cardiac dulness extending 2 inches to the right of the sternum in the fourth intercostal space. Breath sounds were inaudible around the base of the left chest. About the middle of the left chest there was amphoric breathing with a metallic echo. Coin sound through the left chest gave a typical metallic click. There were no rales. Whispered voice over the entire left chest had the same amphoric character as breath sounds. The right chest was normal. There were no succussion and no metallic tinkle. Roentgenoscopy revealed the left chest full of air, the lung being displaced upward and inward, and the heart displaced slightly to the right. This slight displacement of the heart to the right did not accord with the entire absence of cardiac dulness to the left of the sternum.

---

* Read before the Washington Heights Medical Society, April, 1915.

Subsequent History—One week later Temperature, pulse and respiration have always remained normal The patient has felt daily improved Pain on sitting up has become less noticeable Cough on full inspiration is less marked Physical examination has showed continuation of air in left chest, though amphoric sounds in upper chest have become fainter and fainter A few subcrepitant rales have been heard from time to time in the fourth and fifth intercostal spaces just outside the nipple line These entirely cleared There is still no appreciable expansion of the left chest, and cardiac dulness remains to the right

Two weeks later Temperature, pulse and respiration have remained normal throughout the week Left chest has regained an expansion of one-half inch Breath sounds have gradually returned to the left upper chest anteriorly and posteriorly, but are still faint with bronchovesicular character below Cardiac dulness is now elicited 3 inches to the left of the midsternal line in the fifth intercostal space, and heart sounds are now audible to the left of the sternum instead of on the right, as previously

Three weeks later Patient is feeling about normal Roentgen and physical signs show normal chest except for a very small amount of air in left costophrenic chink

Four weeks later Lungs are absolutely clear Heart is normally situated Patient is feeling fine There is no dyspnea or cough

Five weeks later Patient is normal

Six months later Patient is normal

COMMENT

The etiology of pneumothorax in this case must have been one of the following conditions

1 Generation of air within the pleural chink

2 Entrance of air from below the diaphragm or from the esophagus

3 Entrance of air through the chest wall

4 Entrance of air through the lung

In order to be generated within, there must be air-forming organisms present, in which case there would be some fluid and some infection Physical signs and roentgenoscopy show no fluid, and symptoms show no infection The sudden onset of symptoms would also be against infection

Air from below the diaphragm or a hernia would show in the roentgenogram and not heal quickly Esophageal lesion would be detected in the same manner

Air through the chest wall would necessitate some injury such as a stab wound This case shows none

There remains as the causative factor air from the lung There must, then, have been a break in the lung surface This might have been caused by injury, deformity, neoplasm or inflammation Deformity or a neoplasm would have persisted Injury to the surface of the lung would have been due to so great a difference between intrapulmonary and intrapleural pressure as to cause rupture This would not have been sufficient to rupture the lung unless there were some structural weakness brought about by some inflammatory surface lesion Such a lesion might have been tuberculous or nontuberculous Against tuberculosis are the following

No history of tuberculosis in the family, no previous history of tuberculosis in the patient, no subsequent history of tuberculosis in the patient, no symptom or localized sign of tuberculosis, no sign in the roentgenogram, and the acute condition of the case. This, therefore, leaves as the cause some inflammatory lesion of the lung surface, nontuberculous probably, very small with pin point rupture and prompt closure.

MECHANICS

The lungs are suspended within a noncollapsible chest wall They tend to collapse because of their elasticity This collapsing force equals about 4 mm of mercury at the end of expiration and about 8 mm of mercury at the end of inspiration, on forced inspiration it may fall to 30 mm of mercury So long as the glottis is open, allowing free communication with the outside air, there is no greater variation of pressure within the pleural spaces, when the glottis is closed, as in coughing or sneezing, then intrathoracic pressure is increased, also when the glottis is closed during inspiration, then intrathoracic pressure is lessened That the normal lung will stand considerable variation in pressure may be demonstrated by forcibly inflating the excised lungs of a dog with a pair of hand bellows

CONCLUSION

On taking his cold shower the patient may have suddenly taken a deep breath, thus lowering the pressure within the pleural space, rupturing a small point of the lung surface This may also have been brought about by sudden coughing or sneezing Inasmuch as the variations in pressure are not sufficient to rupture a normal lung, there was probably a small focus of nontuberculous softening on the surface of the lung While there was prompt healing of the communication between the intrapleural and intrapulmonary air, it does not seem correct to term the case spontaneous pneumothorax, any more than that a fire of unknown origin should properly be called spontaneous combustion

A CASE OF PHLEBITIS MIGRANS*

Carl A Hedblom, A M, M D, Shanghai, China

A married woman of 26 was in her fourth pregnancy in five years The first two babies had died of marasmus, the third was living and well The husband was in good health There had been no known tuberculosis or cancer in the family Except for measles and scarlet fever in childhood, and malaria five years before, the patient had never been ill General physical examination showed normal findings excepting for rather marked anemia

The patient did not menstruate between the last two pregnancies She presented herself for admission one week before the onset of labor because the "waters had broken" There had been only a little dribble, but it continued in small amounts until labor set in

At admission the temperature was 99.2 Labor pains had begun three hours before The abdominal tumor corresponded to that of an average sized baby in cephalic presentation Only vaginal examination was made seven hours after onset of labor The cervix was found to be three fourths dilated, and the vertex presenting in the occipitolevo-anterior position The labor progressed without incident, and a 7¼ pound baby was born at the end of the twelfth hour by normal mechanism No laceration of the perineum occurred The placenta came away after ten contractions The uterus was atonic, and in spite of ergot and massage there was rather more than the average amount of bleeding, but the pulse did not go above 90

The temperature remained between 99 and 100.2 for the first ten days of an otherwise uneventful convalescence On the eleventh day the patient had a drenching night sweat, and there was a sharp rise of temperature to 104, pulse 110 The breasts were normal, the fundus well down and not tender The white count was 17,000, hemoglobin 60 per cent There was marked tenderness and some induration over the course of the right saphenous vein, and the leg soon became swollen and edematous Treatment consisted in elevation, use of the ice bag, absolute rest, etc After three days there was a marked drop in temperature and pulse, and although the tenderness and swelling extended progressively down to the foot, there was a gradual but steady improvement until the beginning of the fourth week. At this time the temperature again rose sharply to 104.5, pulse 135, and marked tenderness, induration and swelling developed in the right thigh The patient was nauseated a great deal during the next two weeks, vomited at intervals, and complained of pain in the epigastrium much aggravated by food The pulse remained at about 130, became weak and irregular, and there was increasing prostration in spite of the fact that the swelling and tenderness in the legs all but disappeared

---

* From the Hospital of the Harvard Medical School of China

During the sixth week of illness these symptoms recurred first in the left, and then in the right leg, with pain in both legs and feet, which became so severe as to prevent sleep, except after morphin By this time the patient had lost much weight and strength, and several consultants gave a very gloomy prognosis There followed, however, a period of general improvement, during which the patient was again able to take food, and for several days the pulse and temperature remained at about normal During the eighth week induration, tenderness and swelling appeared progressively over the left side of the neck, axilla, arm and left chest There was also increased swelling in the left flank and lower abdominal wall, which was spastic and very tender to palpation The swelling in both legs increased, and pain in the legs and feet became so severe as again to require the administration of morphin The temperature was from 102 to 103, the pulse from 130 to 140 and at times almost impalpable During this recrudescence which lasted about two weeks, gangrene developed over the anterior aspect of both feet, which resulted finally in the separation of the whole thickness of the skin and partial sloughing of the tendon sheaths

After another interval of improvement, there was a fourth relapse, during which the right side of the neck, right axilla and arm became involved, and then successively the occiput, whole scalp and face During the height of this attack, sharp pain developed in the chest, aggravated by deep respiration, but no friction rub or other signs were elicited There were nausea and vomiting lasting several days The voice became husky and the patient complained of severe headache, and pain in all affected parts, but most marked in the feet The symptoms abated toward the end of the tenth week, for a period of about twelve days This was followed by the sixth and last relapse, characterized by abrupt rise of temperature from normal to 102, the pulse was accelerated from 120 to 140, and again became irregular and at times almost impalpable At the beginning of this attack there was a good deal of vomiting and violent headaches The swelling in the neck and scalp, which had begun to subside, also increased After four days the patient became very drowsy, suffered lapses in memory, and finally became partially irrational for several days Ophthalmoscopic examination "Papillitis of both optic nerves Outline of both disks entirely lost Vision almost normal, but patient troubled with duplication of objects" There was no neck rigidity or abnormality of reflexes No food could be taken by mouth, but rectal alimentation was retained At the beginning of the thirteenth week the temperature fell to normal, where it remained The patient became clear mentally and began to take food From this time improvement was slow but uninterrupted The swelling and tenderness gradually disappeared except in the legs, which remained edematous for several months

During the first relapse, blood culture revealed a nonmotile spore-forming bacillus which did not correspond to *B subtilis* in its cultural characteristics An autogenous vaccine was prepared and given in large increasing doses Goat's serum was also prepared from time to time, and injected subcutaneously all without apparent effect The granulations on the feet were grafted by the Thiersch method

The patient was discharged in the nineteenth week in good general condition Nine months after the onset of the illness there was no swelling or disability, the patient was in excellent health and of maximum weight, and was able to play golf and tennis She was admitted two months after this time and an appendectomy done for subacute appendicitis

SUMMARY

In a case of phlebitis, there were involved, successively, and during the course of six fairly definite attacks, both legs, the left flank and abdomen, the chest, the axillae, the arms and hands, both sides of the neck, the scalp and the face, with eye and mental symptoms, complicated by gangrene of both feet There was complete recovery

---

ABORTIVE TREATMENT OF SYPHILIS

JOSEPH J BANSBACH, M D, ST JOSEPH, MO

Oppenheim says that 80 per cent of cases of syphilis can be aborted if treatment is begun in the early stage of the chancre, three or four weeks after infection, when spirochetes are positive, the Wassermann test negative, and no glandular enlargement and chancre can be excised If the chancre is not excised, only 30 per cent can be aborted The abortive treatment consists of four injections of salvarsan and twelve injections of mercuric salicylate given weekly

For the past two years I have used the following combination to destroy the chancre when excision is not possible calomel, 10 parts, zinc sulphate, 10 parts, and chlorin water, 50 parts The combination has a selective action on the chancre, rendering the entire chancre necrotic, and has no effect on the healthy tissue It is applied on a pledget of cotton and covered with the prepuce or a piece of oiled silk and left in place for twenty-four hours In another twenty-four or thirty-six hours the chancre can be lifted out of its bed, leaving a healthy ulcer which heals in a short time under simple dressings I believe this destruction is as effective as excision

The same combination will also destroy a chancroid in one application, converting the soft chancre into a simple ulcer, and reducing the danger of a bubo to a minimum The application causes considerable smarting and swelling of the prepuce, and the patient should be informed that it will do so in order that he may not become frightened and remove the dressing

---

Therapeutics

HEMORRHAGIC DISEASES

(*Continued from page 1701*)

PURPURA HEMORRHAGICA

The name purpura hemorrhagica is often loosely applied to any condition in which there are hemorrhagic spots in the skin It has been used in connection with various idiopathic purpuras such as purpura simplex, characterized by small isolated petechiae in the skin and with either no symptoms or very slight symptoms It has also been wrongly used when petechiae have been present in an arthritic condition such as Schonlein's disease or Henoch's purpura The true purpura hemorrhagica, also known as morbus maculosus of Werlhof, is a clinical entity with characteristic signs, symptoms and blood changes

Purpura hemorrhagica is usually characterized by severe small hemorrhages not only into the skin but also into and from the mucous membranes Cases have been known in which the hemorrhages were confined to the mucous membranes and were absent from the skin In this condition also occur slight or severe constitutional disturbances Fever may be present, and also nausea and vomiting The hemorrhages may be present in any of the mucous membranes, the commonest being the mucosa of the nose with resulting epistaxis There may be hemorrhages from the rectum or from the stomach The orbits and the mucosa of the mouth and throat may be studded with the petechiae In the larger number of cases the skin is involved, and the skin in no part of the body is immune from these hemorrhages The hemorrhages may be present as blebs or as petechiae of varying size

The etiology is unknown It has been attributed to changes in the blood or in the walls of the blood vessels A bacteriologic etiology has never been given much approval, although purpuric conditions have been produced by the injection of different bacteria Such purpuras are not true purpura hemorrhagica, as they are also found in infections and result from the bacteremia

The common belief has been that the disease is caused either by changes in the walls of blood vessels, probably of a degenerative nature, or by some change of the constituents of the blood Pathologic studies show that the alterations in the walls of the blood vessels are not constant Experiments have been tried to produce changes in the vessel walls by injection of toxic substances In some of these, small multiple hemorrhages have resulted, but the evidence obtained has not definitely shown these experimental conditions to be true purpura hemorrhagica There is, however, one constant change in the blood in every case of purpura hemorrhagica This has been very well demonstrated by Duke,[1] who, in a series of cases, studying various factors involved in hemorrhagic disease, found that all of the cases of purpura hemorrhagica showed a marked diminution of the blood platelets Whereas in normal cases the count is between 200,000 and 400,000, in purpura hemorrhagica it is below 10,000, many of the counts even below 1,000, and occasionally nearer zero He found the coagulation time normal and the clot at any bleeding point firm and without retraction In this way a differential diagnosis could be made from hemophilia, in which the blood platelets are normal in number but the coagulation time is delayed

Duke also noticed that the lower the blood platelet count, the more severe were the symptoms In patients with a blood platelet count of 40,000 or over, there was no tendency toward hemorrhage That blood platelets are concerned in some way or other in purpura hemorrhagica has been shown in another way by Ledingham,[2] who was able to produce in guinea-pigs a disease similar to purpura hemorrhagica by the injection of antiblood platelet serum prepared by immunizing rabbits with guinea-pig blood platelets

The conclusions drawn by Duke were substantiated when two cases were transfused directly with immediate relief, and it was concluded that the improvement was due to the increase in blood platelets Emsheimer[3] more recently reported a case of purpura hemorrhagica, in which intramuscular injections of whole blood were given with marked improvement, after other methods had failed He was led to employ this means because the injection of blood is considered to be a stimulus to the production of thromboplastic substances, and the intramuscular method is so much easier and more rapid than transfusion His method was very simple, and consisted of drawing 20 c c of blood from the median cephalic vein of the donor with a syringe and injecting it immediately into the gluteal muscle This was followed by a gradual disappearance of the petechiae and a clearing up of the urine, which had been black at times from the blood contained in it

Howard[4] obtained good results from four subcutaneous injections of whole blood in amounts varying from 28 to 90 c c

Goldstein,[5] in a case of purpura hemorrhagica with marked purpuric blotches in the mouth and spontaneous bleeding from the nose and gums, caused cessation of the bleeding by the subcutaneous injection of 20 c c of antidiphtheritic serum

Frank[6] administers arsenic in conjunction with local or intravenous injection of an extract of blood platelets The blood platelets are contained in normal human blood plasma, which is rich in them About 400 to 500 c c of blood from a donor is collected in a vessel containing herudin (an extract of leech) to prevent coagulation Ten mg of herudin are used for every 75 c c of blood The blood is placed on ice and slowly centrifugalized, after which the plasma is drawn off and used for injection This is all done under strict aseptic conditions Before it is used, blood tests should be conducted to ascertain if there is any hemolytic or agglutinative action of the prepared plasma on the patient's blood corpuscles

Bodenheimer,[7] in a severe case of purpura hemorrhagica, obtained excellent results by the intramuscular injection of horse serum He used 10 c c, and with it he administered calcium lactate in 2 grain doses, every two hours, and gave gelatin by the mouth Hemorrhagic blisters in the mouth showed a marked improvement, and the epistaxis ceased A second administration of 10 c c of horse serum caused the cessation of bleeding by rectum

Another method reported with very good results is the one described by Halpern,[8] in which coagulen is injected subcutaneously Coagulen is prepared from the blood platelets of animals It is a yellow powder, readily soluble in water and not destroyed by sterilizing It may be used intravenously or subcutaneously, and when ready for use, 1 grain is dissolved in 10 c c of distilled water

The most striking results in purpura hemorrhagica were obtained by Ottenberg and Libman[9] by means of transfusions They report nine patients in whom transfusions were made twelve times Of these six recovered completely, and one other left the hospital improved

The prompt cessation of the hemorrhages in all of the patients seemed remarkable The two cases in which there was no improvement were of an unusual form of purpura hemorrhagica, both being post partum It is very likely that their pathogenesis was different from that of the other cases

Thymol.—Thymol was first obtained from thyme—whence its name Commercially it has been made almost entirely from ajowan seed This seed, which grows in northern India, is manufactured into thymol in Europe, chiefly in Germany and France. As soon as the European war broke out thymol became a scarce drug because the war prevented the importation of ajowan seed It is stated that the importations fell from 18 000 pounds in 1914 to a little more than 2 000 pounds in 1915 Now it is announced (U S Department of Agriculture, Bulletin 372) that the production of thymol may be made profitable in the United States the source being the common horsemint (*Monarda punctata*) The government bulletin describes how by cultivation the plants have been improved to a point which, it is said makes the manufacture of thymol from horsemint profitable in the United States

THE RELATION OF THE SPLEEN TO HEMOLYTIC JAUNDICE

Among the positive results which have been described as a sequel to the removal of the spleen are not only an increased resistance of the red blood cells but also a decreased tendency to the jaundice that follows the destruction of these cells by hemolytic agents The spleen is regarded by many investigators as the natural location for the disintegration of erythrocytes after administration of hemolytic poisons[1] The hemoglobin there liberated is carried directly by the portal system to the liver, where it may be in large measure removed, converted into bile pigment, and thereupon excreted in the bile It is readily conceivable that if liberated hemoglobin is thus present in large quantity, some of it may escape this sequence of events, and the pigment appearing in the tissues and the urine may thus produce jaundice Inasmuch as after splenectomy the occurrence of jaundice of this sort appears to be lessened, it may be assumed that in the absence of the spleen the blood cells undergo disintegration elsewhere Their pigment could thus reach the liver indirectly only through the general circulation Traveling in this way, the free hemoglobin would tend to reach the liver much more gradually and at a rate which will lie within the capacity of the hepatic organ for complete excretion as bile pigment, hence no return of the latter into the circulation would occur, and jaundice would fail to develop

The foregoing hypothesis, of course, is not the only one which is suggested in explanation of the lessened tendency to the hemolytic jaundice after splenectomy It may be assumed that some peculiar function of blood cell destruction resides in the spleen, and is consequently lost with the removal of this organ As a matter of fact, hemolytic agents produce disintegration of erythrocytes even in splenectomized animals, though the effect is a *distinctly* lessened one These circumstances have led a group of investigators, in the department of research medicine at the University of Pennsylvania, to inquire whether or not the lessened tendency to jaundice after splenectomy is due, in part at least, to a mechanical factor dependent on the relation of the spleen to the blood supply to the liver

Splenectomy itself has no influence on the fate of hemoglobin injected into the general or portal circulation Bile pigments are formed from at least a part of it Austin and Pepper,[2] under experimental conditions in which hemoglobin was introduced into the blood stream, found that the resulting jaundice was distinctly more persistent after mesenteric than after femoral injection It will be noted that whereas the latter procedure brings the jaundice-provoking substance into the general circulation first, the former path leads directly to the liver The Philadelphia investigators therefore summarize the outcome as follows When the hemoglobin is set free in the portal circulation, a larger amount is held by the liver and converted rapidly into bile pigment than is the case when it is set free in the general circulation Through the direct portal path, overloading of the liver may thus occur more readily, and jaundice is more apt to develop

The purely mechanical influence of the path of entry to the liver must therefore be a factor in the lessened tendency, after splenectomy, to the jaundice which follows blood destruction by hemolytic agents As Austin and Pepper further remark, whether the spleen is an active factor in destroying erythrocytes, or whether it plays merely a passive part as a place for the deposition of the disintegrating cells, there can be no question that in this organ, when it is present, a large number of cells undergo their final disintegration after the action of hemolytic poisons, and that the hemoglobin there liberated passes by the portal system directly to the liver When the spleen is removed, the disintegration occurs in other organs, notably in the lymph nodes and bone marrow, and from these organs the hemoglobin passes not into the portal blood stream but into the general circulation, from which it reaches the liver more gradually and in a more dilute form

The view here presented is fortified by additional experiments in which the venous drainage of the spleen has been altered without the actual removal of this organ Krumbhaar, Musser and Peet[3] have diverted the venous outflow to the liver by the ingenious surgical device of either ligating the splenic vein or transplanting it into the vena cava, instead of removing the spleen Obviously, if the removal of the spleen as an organ furnishing some chemical hormone, is responsible for the effects of splenectomy on jaundice, the usual results obtained with hemolytic agents should not follow when the spleen is left intact in the way described But the animals with transplanted splenic circulation actually show a lessened tendency to jaundice, similar to that exhibited after simple splenectomy This experience thus serves to confirm the probability that the altered course of the blood supply to the liver plays a part in the phenomena discussed

THE NONPROTEIN NITROGENOUS COMPONENTS OF THE BLOOD

If the routine detailed analysis of the blood is to prove of value in the future in the field of diagnosis, as urinary analysis has demonstrated its usefulness in the past, it will be necessary to have elaborate fundamental studies of the normal composition of the circulating fluid and its variations under known conditions of physiologic disturbance Data obtained from this standpoint in respect to the sugar content of the blood have repeatedly been discussed in The Journal[1] Since the introduction of suitable micromethods of analysis, the quantitative aspects of the nonprotein nitrogen of the blood — the index of that fraction of its constituents which includes the circulating amino acids, urea and other products of metabolism — have claimed special attention The technic of the estimations is beginning to share a place in the larger clinical laboratories and is receiving application in particular in the investigation of renal function

An elaborate investigation of the nonprotein nitrogen of the blood recently published by Bang[2] of Lund, Sweden, has brought a confirmation of some of the earlier chemical statistics of the blood as well as an addition to the known facts Thus the average figure for the total nonprotein nitrogen is placed, as the result of numerous new analyses, at 25 mg per hundred gm of blood, out of this an average of 15 mg is apportioned to urea These values correspond fairly closely with those first established in this country for man by Folin and Denis[3] The latter found results varying between the narrow ranges of from 22 to 26 mg for total nonprotein nitrogen and from 11 to 13 mg for urea nitrogen, which lead them to conclude that the perfectly normal kidney maintains a remarkably constant level of these components in the blood

It has been demonstrated that both amino acids and urea, representing food and waste, respectively, from the standpoint of nitrogenous metabolism, occur in the corpuscles as well as in the plasma of the blood,[4] the formed elements being permeable to such compounds An analogous behavior is known in the case of the blood sugar According to the newest analyses of Bang, both the corpuscles and the plasma of human blood as a rule contain practically the same content of total residual nitrogen, urea and amino acids In several instances Bang has observed an increase in the urea content of the blood without any comparable change in the other nonprotein nitrogenous constituents during starvation This was demonstrated, however, to be associated with a lack of water, and disappeared as soon as a suitable intake of water was assured The ingestion of protein did not lead, in Bang's experience, to any noteworthy concentration of amino acids in the blood unless the intake was inordinately large Evidently a renal loss of amino acids is thus averted so long as the blood content does not rise to an excretion level The urea content may be decidedly increased, however, thus showing the speedy conversion of amino acid nitrogen into its characteristic end-product of nitrogenous waste The center of interest in reactions of nitrogenous metabolism is for the time shifting to the study of the chemistry of the blood

NEW RESEARCHES ON THE BILE

Recent progress in our knowledge of the physiology of alimentation has been characterized in particular by a better insight into the mechanism of the secretion of the digestive glands For more or less obvious reasons, the production and properties of the gastric juice have experienced the greatest elucidation Pawlow's epoch-making observations have been followed by numerous others that help to make clear the functions of the various digestive secretions and the activities of the secretory apparatus which produces them

Much has been written about the physiology of the bile, but the literature of the subject still abounds in contradictory statements involving some of its fundamental features There is, accordingly, a peculiar and timely appropriateness to a renewed investigation of the problems of the bile and biliary secretion such as has lately been undertaken in the Institute of Physiology at University College, London[5] Under Starling's leadership it has been shown, contrary to widespread statements, that there is little difference in the effects, on the secretion of bile during the first six or seven hours after meals, between the diets of bread, butter and meat, if these substances are administered in quantities of corresponding caloric value In the case of bread the diminution in secretion occurs sooner than in the case of butter or meat Starvation tends to diminish the secretion of bile and the excitatory effect of feeding on the liver cells

Precisely as special food products are now well known to have a specific effect on gastric secretion, so that meat extractives and dextrins, for example, increase the flow quite pronouncedly and can accordingly be employed in therapeutic ways, certain products also affect the biliary secretion Of white of egg, fats and oils, acids, "peptones," extract of meat, and bile salts or bile, all produce an increased secretion of a more dilute bile, with the exception of bile and bile salts, which produce a bile lighter in color but with a larger percentage of solids Among the substances eaten or introduced into the stomach, on the other hand, producing little or no effect are water, sucrose, cakes of starch and sugar, and sodium bicarbonate As in the case of the pancreas, so with the liver, secretin which finds its way into the circulation promotes the activity of the gland involved, causing in this case the secretion of a more dilute bile Familiar facts in relation to hematogenous jaundice make us ready to understand that injection of the blood pigment hemoglobin into the blood stream increases the pigments of the bile without marked change in the amount This is quite in harmony with the current view that the biliary pigments function as excretory products of hemoglobin

The therapeutic agents capable of promoting the flow of bile are still a subject of controversy About the potency of bile itself as a cholagogue there is no question When fed, as noted above, it causes an unmistakable increase in the secretion Okada[6] has arrived at the conclusion that calomel — the much vaunted drug for biliousness, whatever that may mean — is without effect on biliary secretion, thus confirming other earlier evidence of the same sort Sodium salicylate and chloral hydrate are reported to provoke biliary flow markedly, phenyl salicylate (salol), cream of tartar, and alcohol in large doses are likewise reported to be distinct stimulants, atropin causes a slight diminution of secretion

When a meal is taken, the ejection of the chyme into the duodenum is followed by an ejection of bile as the result of contractions of the gallbladder According to Okada's newest observations, during digestion there is an increase in the force of the rhythmic contractions of the gallbladder

The reaction of the different alimentary secretions is a matter of considerable physiologic significance, and about this aspect of the bile, also, the statements are anything but concordant The older methods of estimating the reaction have given way to the more exact procedure of determining true acidity or alkalinity in terms of hydrogen ion concentration It is now evident that the reaction of the bile from the gallbladder and from the liver is different, the reaction of the former is more variable and always inclining more to the acid side than that of the latter[6] Okada has pointed out that the facts that bile, in so many animals, is poured into the intestine by an orifice common to it and the pancreatic juice, and that these two fluids cooperate in their actions on the ingested foodstuffs, suggest that they must have a reaction which is optimal for their action in the processes of digestion As a matter of fact, the reaction of bile from the liver is alkaline during digestion and corresponds to that of pancreatic and intestinal juices and with the optimal point for trypsin, pancreatic lipase and erepsin

THE CAUSE OF TYPHUS FEVER

Much progress has been made in recent years in solving the problem of the cause of typhus fever Perhaps the most important demonstration from a practical point of view is the discovery by Nicolle, Ricketts and others that the disease is transmitted by the body louse The demonstration also that apes, monkeys and guinea-pigs are susceptible to the typhus virus makes it possible to conduct systematic experiments on animals, and in the course of such experiments it has been shown quite conclusively that the disease is not caused by a filterable virus as we ordinarily understand it And so the search for a bacterial cause has continued

In 1914, Plotz described a gram-positive anaerobic bacillus obtained in culture of the blood from patients with endemic typhus in New York and of typhus fever in immigrants in quarantine The medium consisted of glucose agar and unheated, unfiltered ascitic fluid with a specific gravity of about 1 015 Subsequently the same bacillus was recovered from guinea-pigs and monkeys inoculated with typhus blood, and specific agglutination and complement fixation obtained with the blood typhus patients after the crisis The evidence is consequently strongly in favor of at least some close relationship between this bacillus — the *Bacillus typhi-exanthematici* — and typhus fever, it can hardly be asserted, however, that it has been demonstrated conclusively to be the specific cause of typhus fever It is not apparent that injections of this bacillus in animals give rise to the same reactions which occur after the injection of typhus blood, of course it must be acknowledged that failure to produce reaction and failure to protect animals against the virus in typhus blood do not necessarily imply that the bacillus is not the cause of typhus, but they make the demonstration of the true relation of this bacillus to typhus fever difficult

---

[6] Okada, S On the Reaction of Bile, Jour Physiol, 1915, L 114

The extensive outbreaks of typhus in European countries involved in the war, especially Serbia, would seem to offer unexcelled opportunity for the further work necessary to settle the etiologic problem of this disease, in spite of the abundance of the material, however, the conditions in war do not seem to be favorable for scientific investigation Thus we are informed that the American Red Cross Commission found it practically impossible to do systematic work during the last typhus epidemic in Serbia, and the recent work in Mexico by Olitsky[1] and others was interrupted very soon after it had been started From the latest Mexican work we see that the results again indicate the close relationship between the bacillus of Plotz and typhus, and we may hope that independent workers under favorable conditions will secure results before long of definite significance

In connection with this work on typhus we note the melancholy fact that another investigator has died from the disease Carlos E Husk died, March 20, 1915, from typhus fever contracted in the course of the work mentioned in the foregoing There is probably no disease that has claimed so many victims among physicians and nurses as typhus It is said that during twenty-five years, of 1,230 physicians attached to institutions in Ireland, 550 died of typhus Since the war, again, typhus has claimed many victims from physicians, among them, for instance, Jochmann, who was doing splendid work in the study of infectious diseases And the martyr roll of typhus now includes three American investigators who have died from typhus contracted while voluntarily investigating the disease in Mexico — Conneff of the Ohio State University expedition, Ricketts, who accomplished so much, and now Husk

FEVER-PRODUCING SUBSTANCES — PYROGENS

The scientific literature on fever, considered as a pathologic phenomenon quite independent of the ulterior cause, abounds in the rival claims of the so-called toxogenic and neurogenic theories Virchow, as early as 1853, looked on fever as a neurosis — the condition being considered analogous to a paralytic state, with a failure of the control of some physiologic processes in the organism This attitude has been attacked particularly on the ground that there is no very definite proof of the existence of special nerves which preside over the production of heat Accordingly, it has seemed more likely to many students of fever that circulating poisons affect directly all the cells of the body, so that the latter react with a febrile intensification of their metabolism[2] A peculiar significance was given to the toxogenic theory, particularly with reference to the reported results of the fever-producing effects of extracts of certain tissues and other substances, by the observations of Hort and Penfold[3] in 1911 These showed that when ordinary water, after it is sterilized, is injected intravenously into rabbits, the result is usually a short febrile reaction, whereas the injection of pure sterile water, carefully distilled from glass, fails to produce such a result This work has in the main been corroborated

Evidently, then, water may readily be contaminated with micro-organisms which produce some pyrogenic substance which is not destroyed by the heat employed in sterilization From a practical standpoint this fact has emphasized the necessity of using freshly distilled (as well as sterilized) water for the preparation of fluids for injection On the theoretical side, moreover, it suggests the existence of relatively stable substances which must require a dosage extremely small at best to produce febrile responses independent of the introduction of living organisms into the body

In harmony with this are the more recent experiments of Jona[4] at the Lister Institute in London From *Bacillus coli* he obtained a substance of remarkable potency On injection in a minimal amount of Ringer's solution, fever or collapse can be produced by it in experimental animals, a dose equivalent to 0 000004 gm of bacterial bodies producing fever, and 0 002 gm producing marked collapse or even death The dosage feature becomes even more striking on contemplation of the fact that the bulk of the weight of the bacteria must be something other than the incidental pyrogenic substance yielded by them According to Jona, the substance or substances in the bacteria responsible for the rise in temperature are either of a colloidal nature or adherent to colloids, so that they may be almost entirely removed by a collodion filter They are not destroyed in boiling water or by dry heat of 110 C (230 F), and they are insoluble in organic solvents such as alcohol and ether The rise in temperature ordinarily produced by these products (in rabbits) lasts a few hours, and is principally due to a diminution in heat loss, the heat production remaining sometimes unaffected and sometimes increased

On the basis of such facts, some of the reputed pyrogenic effects attributed to a variety of substances — proteoses, enzymes, etc — may perhaps find an explanation in their association with these subtle impurities of bacterial origin Although Krehl and others have long claimed fever-producing properties for digestion products of ordinary proteins, Gibson[5] has shown that only slight, if any, pyrogenic effects are produced with carefully purified proteoses He concludes, therefore, that any rise in temperature which may have been observed is insufficient to warrant the opinion that proteoses cause the severe natural fevers If we are dealing with impurities in such reputed cases of fever-producing products, it is nevertheless possible, according to Jona, that in cases of burns to the body, substances of a nature similar to the bacterial "pyrogen" are set free and may give rise to the fever seen in milder cases as well as the collapse in the severer ones All suggestions of this character contribute to the probability of toxogenic factors which deserve wider consideration in the speculations of the future on the subject of febrile reactions

Current Comment

NONSPECIFIC FACTORS IN THE TREATMENT OF DISEASE

There is a growing interest in the scientific investigation of the nonspecific elements in recovery from infectious disease, and a close examination of clinical facts suggests that some of the therapeutic effects which have been attributed to action, specific in the sense of Ehrlich, may have resulted from physicochemical changes of a less specific and more general nature Jobling and Petersen[1] review the evidence, both clinical and laboratory, which points to the importance of nonspecific elements in biologic therapeutic reaction, and suggest that in the past we have adhered perhaps too closely to the narrow view of specificity, and have refused to consider evidence of nonspecific therapeutic results, particularly if such observations originate from clinical sources They then discuss some of the ways in which nonspecific effects become evident clinically by hyperpyrexia, by leukocytosis and by laboratory tests for changes in the serum suggesting the mobilization of ferments While this discussion is timely, a word of caution may not be amiss While it is probable that much important information will come out of this line of investigation, our present information is meager, and we must not at once cast aside all of our conceptions of specificity in disease, for it is under the guidance of these conceptions that we have made progress up to the present time Nor does it seem wise to accept clinical evidence alone as conclusive, unless confirmed by many observers under varying conditions Miller and Lusk,[2] in a paper dealing with one phase of such nonspecific therapy, report improvement lasting as long as five weeks in patients suffering from arthritis, following intravenous injections of typhoid vaccine These observations afford an example of what appears to be a favorable nonspecific therapeutic action of foreign protein It would be of interest, however, to know how permanent the improvement in these patients was, and in how many the cause of the arthritis was found and removed Finally, we must bear in mind the query propounded by Theobald Smith in another connection How much energy does a reaction of this sort cost the patient, and is the final result worth the cost?

MINERS' NYSTAGMUS

In view of the enactment of the workmen's compensation laws in more than thirty states, miners' nystagmus may at any moment become of immediate interest No investigation has been made in the United States (except in Illinois) as to the existence of this disease, still less has a thorough survey been undertaken The Bureau of Mines has recently published a monograph by Frederick L Hoffman[1] in which are reviewed the various opinions as to the causation and prevention of nystagmus It is estimated that, if cases of nystagmus occurred in American mines to the same degree as they do in Europe, there should be a number of cases each year which may be estimated as between 25,000 and 40,000 It would seem improbable that such a large number could escape notice, but experience in Europe has shown that very little attention is paid to the disease until it becomes a question of compensation The conditions to which the occurrence of nystagmus are generally attributed are rare in this country These are hand undercutting, the working of extremely narrow seams, and entire dependence on the feeble light of the miners' lamp But it must be remembered that, according to Elworthy, the true determining cause is total absence of color in coal mines, combined with the fact that the majority of miners prefer to work in daytime, so that they have very little opportunity for relief of the retina This view is to a certain extent supported by the absence of nystagmus in miners working in mines other than coal mines under conditions which should produce nystagmus, except that the monotonous blackness is absent In this respect, it would be interesting to know what is the condition as to nystagmus of the miners of Mansfeld, whose copper seams are notoriously the thinnest in the world, and who work in inconceivably cramped quarters

GOA POWDER AND CHRYSAROBIN

Among the drugs which have increased in price since the outbreak of the war in Europe is chrysarobin, which, formerly about $3 a pound, wholesale, is now, when quoted at all, held at $6 75 a pound[2] Chrysarobin, widely used in psoriasis, is manufactured from goa or araroba powder, which is said to come entirely from the American continent — from the state of Bahia, Brazil According to a report by Consul Robert Frazer, Jr,[3] this substance is found in the form of a pulp or small solid masses, supposed to constitute a morbid growth, in crevices of the heart wood of a leguminous tree known locally as *amargoso do matto*

Schmidt and L Saurenhaus Unit No 4 which sailed for Europe from New York on the *New Amsterdam*, May 27, is in charge of Dr John R McDill, Milwaukee, Wis, and the other medical members of the units are Drs Frank Hegler St Louis, Edmund H Mensing, Rochester, Minn, and Harry C Rolnick, Chicago together with four nurses This unit is assigned to duty in Germany Unit No 5, which sailed from New York on the *Frederick*, May 31, is to work in Austria and is in charge of Dr Paul F Martin Indianapolis whose assistants are Drs W H Moore Indianapolis, and Drs Jacob J Minke, and George E Kirby, Chicago, with three nurses from Chicago and one from Indianapolis

LONDON LETTER

London, May 15, 1916

The War

THE SUPPLY OF MEDICAL OFFICERS

The adoption by Parliament of conscription for all men between the ages of 18 and 41 has altered the problem of obtaining sufficient medical officers for the army Curiously, a physician cannot be compelled to serve in his professional capacity, but only as a combatant Needless to say, he is not likely to choose the latter when his services are required in the former capacity Under the enrolment scheme of the Central Medical War Committee, described in previous letters to The Journal, a pledge was given that physicians who enroll would not be called up until 75 per cent of the possible constituency had enrolled But before this percentage had been reached, the War Office asked for more medical officers, which must render the keeping of the pledge difficult unless, in order to avoid combatant service, more physicians enroll

THE DUBLIN REBELLION

The short-lived Dublin rebellion was responsible for a large number of casualties, of which 521 occurred among the soldiers police and loyal volunteers Of these 133 were fatal There is no means of estimating the casualties among the rebels, who concealed them when possible, but they must have considerably exceeded those on the other side The number of civilians reported as dead in the hospital amounted to 160 How many of these were harmless civilians shot in the streets and how many were rebels is not known, as many of the latter did not wear uniform, or may have exchanged it for civil attire A very sudden strain was imposed on the Dublin hospitals near the fighting area, to which they responded admirably One hospital, the Richmond, was seized by the rebels, and three of the visiting staff who happened to be there were kept prisoners for a whole week. The rebels brought their wounded into this hospital and removed them as soon as they could Many physicians and nurses were absent from Dublin on the Easter Monday of the outbreak, but they returned as rapidly as possible to their posts From Monday to Sunday the medical staffs worked almost incessantly, and the Red Cross and St John Ambulance organizations did splendid work in removing the wounded under fire The rebels respected the Red Cross but in the darkness men bearers were unrecognizable and fired on Then the nurses repeatedly ran out with stretchers and carried in the wounded To add to the horrors, the immense fire which devastated Sackville Street crept nearer and nearer to the Jervis Street hospital, causing great anxiety, but fortunately the building escaped In this hospital, as well as in the Mater Misericordiae, the staffs were for days virtual prisoners, because of the danger of passing through the streets Many of the hospitals were repeatedly struck by bullets, and one was threatened by the fire of a big gun, the officer in charge of which was unaware of the proximity of the hospital As the city gas supply was cut off early in the week, operative work in the hospitals was rendered very difficult One ambulance worker was killed and also one nurse, and three army surgeons were wounded One of the buildings occupied by the rebels was the Royal College of Surgeons Little damage was done, however, some of the windows were riddled by rifle and machine gun fire and some damage was done to the walls and furniture Some of the library books were taken to form barricades, and were more or less damaged The ammunition used by the rebels was of all kinds from the modern nickel-covered rifle bullets to large soft lead bullets with the point cut off, and even 12-bore cartridges filled with buckshot and slugs Some of the wounds inflicted on the military were consequently severe, especially those traversing the chest and head At the Royal City of Dublin Hospital all the wounds were washed with hypochlorite solution, and extensive wounds were left open and packed with gauze wet with hypochlorite solution, the surrounding skin being in all cases painted with tincture of iodin This treatment appears to have been successful, even extensive wounds usually healing without much sepsis Proximity to the hospitals gave the great advantage of early operation In one case a man was brought into the Royal City of Dublin Hospital within half an hour of being shot in the back, the bullet had emerged under the right costal margin He was immediately taken to the theater and the abdomen was opened the right lobe of the liver was so extensively torn that it was impossible to suture it, but by packing both the torn cavity and all around they were able to check the hemorrhage, and the patient is now recovering.

CEREBROSPINAL MENINGITIS AMONG TROOPS

An important report on the epidemic of cerebrospinal fever among the British and Canadian troops stationed in England during the latter part of 1914 has just been issued. During the years 1913 and 1914, cerebrospinal fever prevailed in this country to a somewhat greater extent than had previously been experienced, and in the first half of the year 1915 this increase assumed large proportions. In 1913, 305 cases were reported, and in 1914, 315. In 1915 the number of cases in the civil population had increased to 2,565. This increase coincided with the military mobilization of a large part of the male population. Although the disease was present in England and Wales during 1914, and before that time, it is suggested that a fresh strain of infection was brought from Canada at the end of 1914 to this country by the first Canadian contingent which came to Salisbury Plain to undergo their final military training. It appears that cases had occurred among the Canadians in their camp at Valcartier before embarkation, and that other attacks occurred among them during the voyage to this country and just after their arrival. About twenty-nine cases had been observed among the Canadian troops up to the middle of February, and twenty-five had proved fatal. The predisposition to this infection may perhaps have been increased by the unavoidable overcrowding in camp, which at first took place, as also by the occurrence of cold, wet and inclement weather, and by the unusual exertion and fatigue incidental to the military training of young recruits. No fewer than 2,290 cases were reported in the civil population from January to July, 1915, and 1,088 among the military, a total of 3,378 cases in seven months.

WOMEN PHARMACISTS

The war has caused a large increase in the number of women students of pharmacy, and at present there are as many women students as men at some of the principal schools of pharmacy. Before the war there were at the most only a few hundred women on the pharmacists' register, and very few were actually employed in shops. Now such is the demand for women assistants to take the place of young men that a woman pharmacist who advertises for an appointment receives several offers at salaries ranging from $500 to $1,000 a year.

Clean Milk

At a meeting of the National Clean Milk Society, Sir Thomas Barlow spoke on the failure of the various tests to produce a good imitation of mother's milk during the past twenty-five years, the greater number of infants' foods being deficient in fats. There should be as little tinkering as possible with food intended for children. As the sterilization of milk and the use of dried foods spread in upper class nurseries, infantile scurvy was seen. Milk should be pure, even if it was sometimes diluted or modified, but it must not be tinkered with. There must be cleanliness of the byre, the cow, the cow's food, the vessels from which it drinks, and the hands of the milker.

Mr. Wilfred Bucklet, chairman of the Council of the Society, said that within the last forty-eight hours he had had a sample of certified milk tested at the Lister Institute, which contained 12,500,000 bacteria to the cubic centimeter. After describing the dangerously unclean conditions under which milk was produced on farms, he said that he had seen a man bottling milk over a gutter and pulling the covering disks from his pocket. In New York four years ago twenty-four men were imprisoned without the option of a fine for bottling in the streets. The society was advocating the use of the score card system of dairy farm inspection by local authorities as in America, where marks were given for milking with a dry hand, among other things. This has been already introduced in Bradford and in Birmingham, and was being considered in Manchester. They were advocating that assistance should be given to owners of herds who wished to free them from tuberculosis, and they wished to induce railway companies to provide refrigerated cars to be used solely for the transportation of milk and to offer reasonable rates for the carriage of milk in bottles or other special vessels. It was sought also to make it illegal to open churns in transit and to promote compulsory annual licensing of all dairy farms and milk shops. The society was also advocating the authorization by legislation of definition of a grade of milk inferior to "certified" milk, which shall be produced from herds free from tuberculosis and contain not more than 60,000 bacteria per cubic foot.

PARIS LETTER

Paris, May 4, 1916.

The War

A NEW SOCIETY FOR MILITARY SURGEONS

In previous letters I have spoken of the formation of several societies composed of military surgeons for the discussion of medical and surgical questions raised by the war. In addition to societies of this kind connected with the armies, others have been formed in the interior. Thus, at a recent meeting of military surgeons of the sixteenth region, which includes the five departments of Herault, Aude, Lozere, Tarn and the Pyrénees-Orientales, it was decided to have a medico-chirurgical meeting twice a month at Montpellier. In view of the special object of these meetings, which is the interchange of medical and surgical knowledge particularly useful to military surgeons, the scientific side of the discussions will not be developed to the exclusion of their utilitarian aspect. It is intended the morning after each meeting to have practical lectures and demonstrations in the service of one of the "specialist" centers. In order to facilitate the attendance of the practitioners of the region at these meetings, the regional director of the public health service intends to give leave of forty-eight hours as freely as the necessities of the service will permit it. The proceedings of these meetings will be published in the *Montpellier medical*, which will reappear for this special purpose (it has ceased publication since the commencement of the war). Membership in the society will include subscription to the journal. Each member will make a small three-monthly payment, varying with his rank. This is, exclusively, to cover the cost of printing and mailing the *Montpellier médical*.

A RUSSIAN MEDICAL MISSION IN FRANCE

The union of the Russian zemstvos has sent a mission to study the general organization of the French medical service, both in the provinces and in the armies. This mission is engaged in the study of the public health service in Paris, of the Saint-Maurice school for the reeducation of cripples, of the blind asylum at Reuilly, of the convalescent home at Clignancourt and of the Pasteur Institute. It will next visit the 14th region (Lyons), and thence it will go to the front.

HELP FOR THE BLINDED VICTIMS OF THE WAR

A new organization called L'Aide aux aveugles de guerre, with headquarters at 2 Rue Balzac at Paris, has just been formed. The object is to get into touch with blinded soldiers whether reeducated or not, with a view to providing them with immediate moral and material support and also to investigate the means available to remedy as far as possible the misfortunes of these victims of the war.

VACATION ARRANGEMENTS FOR THE RED CROSS NURSES

Several owners of large hotels in Switzerland are offering to ladies of the French Red Cross accommodation at exceptionally low prices during the months of July, August and September. Under arrangements made by a committee of Swiss lady patrons, the choice of the nurses, who are to benefit by this arrangement which permits of a stay of three weeks, will be made by the French Red Cross committees. M. Gustave Ador has accepted the honorary presidency of this new organization.

VALUE OF VARIOUS DRESSINGS IN WAR SURGERY

Dr. Le Fur has communicated to the Societe de medecine de Paris his observations of eighteen months of dressings in war surgery. In the first place, with the exception of certain bullet wounds which remain aseptic throughout, war wounds are, as a rule, seriously infected and antisepsis and not asepsis is required. Simple aseptic dressings are wholly useless in the majority of such cases, especially in wounds due to shell fragments complicated by bone or joint injuries. Among the antiseptics which have given the best results in Le Für's practice are hydrogen peroxid, dilute solutions of silver nitrate (for sloughing and suppurating wounds) phenol solutions and various chlorinated solutions (Labarraque's solution and Javelle water). He advises, after thorough washing with one of these, the application of wick drains saturated with concentrated solutions. In case of excessive suppuration, free drainage, continuous aspiration and sometimes continuous irrigation are indicated; finally when the wound is well disinfected and exposed freely, wet aseptic dressings, using common salt solution, chloroform water, very dilute silver nitrate or dry dressings to hasten cicatrization (iodin and zinc peroxid). Indolent wounds should be stimulated by hot air and especially by exposure to the sun (heliotherapy) Long standing fistulas should be cauterized energetically with zinc chlorid or silver nitrate it is sometimes advisable, after scrupulous disinfection, to close them by paraffin or one of the special waxes made for this purpose, this is especially the case in bony cavities If they persist, they must be curetted or excised In case of pleural suppuration and fistula the ordinary dressing must be supplemented by ether wick drains to promote drying and especially, by respiratory gymnastics It is very important in old wounds to vary the dressing, as the benefit obtainable from one kind of dressing, frequently repeated seems to be rapidly exhausted

Death of Professor Jungfleisch

M Jungfleisch professor of organic chemistry at the College de France is dead at the age of 77 Born in Paris in 1839, Jungfleisch was for more than thirty years professor at the Ecole superieure de pharmacie de Paris His work on organic chemistry written in collaboration with Berthelot had at one time a great vogue in scientific circles Jungfleisch was a member of the chemical section of the Academie des sciences and since 1880 a member of the pharmaceutical section of the Academie de medecine

Anaphylaxis and Prophylactic Injections of Antidiphtheric Serum

The minister of the interior having requested the Academie de medecine to report to him on the accidents following the injection of antidiphtheric serum Dr Netter of the Faculte de medecine de Paris has deposited a report on this subject in which he puts the matter in its proper perspective The fear of these accidents, which is very widespread, both in the medical profession and among the people has too often formed an obstacle to the use of the serum in cases in which this was absolutely necessary Still more has it obstructed the use of antitoxin for prophylaxis It is of course, known that disagreeable sequelae and even death have been observed as the result of a single injection With injections spaced out at intervals of more than ten days these accidents are more immediate and more alarming This is the phenomenon of anaphylaxis Nevertheless, serum anaphylaxis is far less frequent and less grave in man than in the guinea-pig In children after subcutaneous injections serious results are extremely rare Only two well proved deaths are known as the result of several hundred thousand reinjections It will not be reasonable therefore because of these altogether exceptional dangers, to give up reinjections and still less, first injections Experiment has shown that in animals, which have previously received horse serum antitoxins introduced in later injections are very rapidly eliminated There has been a tendency to conclude from this that a previous injection diminishes the efficacy of new ones A study of the course of 123 cases of diphtheria occurring in persons who had previously received curative or preventive injections, has shown that there is no foundation for this apprehension The ill effects of therapeutic serums can be attenuated or warded off by various means Whenever possible for reinjection and even for first injections, one should use Besredka's method, that is to say, commence by the injections of extremely small quantities of serum

The preventive efficacy of antidiphtheric serum was fully confirmed last year in the schools of the department of the Seine where, on the initiative of Dr Dubief, 2,582 prophylactic injections were given

The Academie de médecine considering Netter's report, passed unanimously the following resolutions

1 Serious accidents caused by a first injection (serum sickness) or by a reinjection (anaphylaxis) are very rare, especially if the injection is made into the subcutaneous cellular tissue The fear of such results should never be allowed to interfere with the use of serotherapy

2 The Academie de medecine maintains with regard to the advisability of prophylactic injections of antidiphtheric serums, the opinion which it pronounced in 1902 These injections should be practiced on children in all families or institutions in which cases of diphtheria have occurred They should also be recommended in children's schools when diphtheria assumes an epidemic character The academie is of the opinion that concurrently with these injections disinfections isolation of the sick, and the searching for, isolation and treatment of carriers should be carried out whenever possible

Association News

THE DETROIT SESSION

Hotel Reservations

LOCAL COMMITTEE REQUESTS CONFIRMATIONS

The Committee on Arrangements for the Detroit session reports that it desires to take every precaution against errors and confusion in arranging for the accommodation of those who attend the coming annual session In order to do this the committee requests the cooperation of the physicians who have made hotel reservations and have been asked by the hotel management to confirm these It will be of assistance in guaranteeing such reservations if those who hold these will make reply to the request of the hotel management that these reservations be confirmed

In addition, the local committee will appreciate it if those who hold reservations but who will not be in attendance at this coming session will write to the subcommittee on hotels addressing Dr Rolland Parmeter, 33 East High Street Detroit, returning the slips which have been forwarded assigning hotel reservations

SPECIAL TRAIN FROM ST LOUIS TO DETROIT

The outlook is promising for a special train from St Louis to Detroit for Fellows and their wives from Missouri Arkansas Kansas Oklahoma and Texas The train will leave via the Wabash Railroad Sunday, June 11, about 6 30 p m., arriving in Detroit Monday, June 12, 7 30 a m Option of return via Chicago without additional fare, or return via lake steamer from Detroit to Chicago for $5 additional fare All passing through St Louis en route to Detroit with tickets over the Wabash Railroad are invited to reserve space on this special train Communications should be addressed to Dr Edward J Goodwin, 3517 Pine Street, St Louis

PHYSICIANS' SPECIAL LAKE CRUISE

The Steamer *South American* will leave Chicago Saturday June 10 arriving in Detroit Monday, June 12 The rate is $30 and includes transportation, meals and berth en route Chicago to Detroit also use of state room and berth and breakfast while steamer is at Detroit, June 12, 13, 14 and 15

Passengers leave steamer after breakfast Thursday morning June 15 The steamer does not return to Chicago after the meeting

The round trip rate by boat Chicago to Detroit, and rail Detroit to Chicago, is $36 80

At time reservations are made passengers may purchase one way or round trip tickets

DETROIT CLINICS

From June 7 to 12, inclusive, and on June 17, a series of clinics will be given in Detroit Those attending the Detroit Session are invited to these clinics Programs can be obtained from the Local Committee on Arrangements, 33 High Street East, Detroit

Marriages

P A Surg Cary Travers Grayson, U S Navy, to Miss Alice Gertrude Gordon of Washington in New York City, May 24

Francois John Theodorus Was M D., Chicago, to Miss Josephine Von Swartzenberg of Paterson N J, May 20

William Carl Goenne, M D, Eldridge, Iowa, to Miss Norma Otto of Davenport, May 24

Fred August Thysell M D, to Miss Myrtle Graham, both of Rhinelander, Wis May 10

Charles Stoltz M D to Miss Mary Lou Foster, both of South Bend Ind May 17

John A Tamisiea M D, to Miss Mary E. Burns, at Omaha, May 12

Deaths

Col John Leighton Phillips, M C, U S Army, Takoma Park, D C, aged 57, commanding the Walter Reed General Hospital, Takoma Park, D C, a Fellow of the American Medical Association, died in the grounds of that institution, May 23, from the effects of a gunshot wound of the heart, self-inflicted, it is believed, with suicidal intent, while despondent on account of ill health, the result of a fall three or four months before Colonel Phillips was a native of Chapel Hill, N C, was graduated from the College of Physicians and Surgeons in the City of New York in 1882, entered the army as assistant surgeon a year later, was made captain and assistant surgeon in 1888, major and surgeon in 1900, lieutenant colonel in 1908 and was promoted to colonel, April 13, 1912, and served for three years as assistant chief sanitary officer of the Isthmian Canal Commission and chief surgeon of the Ancon Hospital

John Chamberlain Hollister, M D, Pasadena, Calif, Northwestern University Medical School, Chicago, 1900, aged 43, formerly a Fellow of the American Medical Association, a member of the Medical Society of the State of California, Chicago Surgical Society and a fellow of the American College of Surgeons, formerly instructor in gynecology in his alma mater and assistant professor of gynecology and surgery in the University of California, for several years a practitioner of Chicago, surgeon to the Home for Crippled and Destitute Children, adjunct surgeon to St Luke's Hospital and surgeon to St Luke's Hospital and Dispensary, died at his home May 6, from pneumonia

Elmer M Brown, M D, Tacoma, Wash, Willamette University, Portland, Ore, 1879, aged 58, a Fellow of the American Medical Association, a member of the North Pacific Surgical Association and a Fellow of the American College of Surgeons, surgeon of United States Volunteers during the Spanish-American War with service in the Philippine Islands, at one time health officer of Tacoma and physician of Washington County, Ore, dean of the medical profession of Tacoma and prominent in civic work, died at his home, May 12, from carcinoma of the superior maxilla

Lieut Luther Mitchell Ferguson, M R C, U S Army, on duty at the Walter Reed General Hospital, Takoma Park, D C, aged 27, died, May 23, in that institution, from the effects of injuries received in a fall from his horse He was born in Chin Kiang, China, July 2, 1888, and was graduated from Harvard Medical School in 1915 He was graduated from the Army Medical School in 1916 He was a Fellow of the American Medical Association and a member of the Association of Military Surgeons of the United States

Robert Lee Bowcock, M D, Anniston, Ala, University of Virginia, Charlottesville, 1886, a member of the Medical Society of Virginia and International Association of Railway Surgeons, and formerly president of the Calhoun County (Ala) Medical Society, Board of Health, and Medical Examining Board, local surgeon of the Southern Railway and division surgeon of the Louisville and Nashville System, died at his home, May 16, from pneumonia

William Hillkowitz, M D, Cincinnati, Medical College of Ohio Cincinnati, 1888, aged 49, a Fellow of the American Medical Association, and a member of the Cincinnati Academy of Medicine, physician to the Jewish Foster Home and consulting obstetrician to the Ladies' Society for the Relief of the Sick Poor and the United Jewish Charities, died at the Bethesda Hospital, Cincinnati, May 14, from heart disease

William M Harvey, M D, Detroit, Detroit College of Medicine and Surgery, 1887, aged 52, formerly a Fellow of the American Medical Association, a member of the Michigan State Medical Society, for eight years city physician of Detroit and for twelve years a major in the Medical Corps of the Michigan National Guard, died at his home in Grosse Pointe, Mich, May 13, from cerebral hemorrhage

S M LeCrone, M D, Tacoma, Wash, Starling Medical College, Columbus, Ohio, 1878, aged 69, for five years a member of the board of health of Columbus and later assistant city physician, president of the Washington State Pharmaceutical Association in 1904, a member of the Washington Legislature in 1899 and 1903, died at his home, May 17, from arteriosclerosis

Ralph Aaron Grigsby, M D, Scottsbluff, Neb, Tulane University, New Orleans, 1905, aged 33, a Fellow of the American Medical Association, died at his home, May 5, from postpharyngeal abscess

Clarence Percival Bulson, M D, New York City, College of Physicians and Surgeons in the City of New York, 1896, aged 50, also a graduate in pharmacy, formerly a member of the staff of St Luke's and Harlem hospitals, died at his home, May 18

Frank A Jordan, M D, Pecatonica, Ill, Rush Medical College, 1864, aged 76, a veteran of the Civil War in which he served as assistant surgeon of volunteers, died at the home of his daughter in Freeport, Ill, May 15, from cerebral hemorrhage

William H Gibbins, M D, Clinton, Mo, Medical College of Ohio, Cincinnati, 1873, aged 64, a member of the Missouri State Medical Association and for many years president of the Clinton School Board, died at his home, May 15

Edward R Bragg, M D, Biloxi, Miss, Tulane University, New Orleans, 1888, aged 54, formerly a Fellow of the American Medical Association, for several years a physician in the Isthmian Canal Zone, died at his home in Biloxi, May 12

Edgar Rush Burns, M D, El Paso, Texas, Chattanooga (Tenn) Medical College, 1901, aged 41, formerly a practitioner of Cullnan, Ala, and a member of the Medical Association of the State of Alabama, died at his home, May 10

George L Hoel, M D, Fort Collins, Colo, Barnes Medical College, St Louis, 1898, aged 54, a Fellow of the American Medical Association, was killed in an automobile accident at Fort Collins, May 22

Guy Marion Black, M D., Pocahontas, Ark, College of Physicians and Surgeons, Memphis, Tenn, 1910, aged 40, a member of the Arkansas Medical Society, died at his home, May 12, from heart disease

Thomas A Welch, M D, Groesbeck, Texas, Tulane University, New Orleans, 1897, aged 46, a Fellow of the American Medical Association, died at the home of his sister in Groesbeck, May 11

John Preston Deckard, M D., Mattoon, Ill, University of Louisville, Ky, 1880, aged 59, a member of the Illinois State Medical Society, died at his home, May 13, from cerebral hemorrhage

Louis Young, Wise River, Mont, (license, Montana, 1874), for forty years a practitioner of Orleans, Vt, aged 75, died in a hospital in Butte, Mont., May 17, from malignant disease

John George Horne, Coffeyville, Kan, (license, Kansas, 1901), aged 58, a practitioner for thirty-five years, died at his home, May 16, from carcinoma of the stomach

Joseph H Jones, Fort Wayne, Ind, (license, Indiana, 1897), aged 84, for more than fifty years totally blind, died at his home, May 17, from heart disease

James Evert Simmons, M D, Rockport, W Va, University of Louisville, Ky, 1909, aged 27, died suddenly at his home, April 21, from heart disease.

James W Reader, M D, Maryhill, Wash, Rush Medical College, 1870, a veteran of the Civil War, died at his home, May 16

Norman K Morris, M D, Denver, Cleveland University of Medicine and Surgery, 1876, aged 64, died at his home May 12, from cerebral hemorrhage

Thomas Clayton McCarty, Spottsville, Ky (license, Kentucky, examination and twenty-seven years of practice, 1894), aged 76, died at his home, May 10

Frank Grider, M D, McKinney, Ky, University of Tennessee, Nashville, 1892, aged 48, died at his home, May 10, from cerebral hemorrhage

Joseph Jones, M D, Stockbridge, Mass, Eclectic Medical College of Philadelphia, 1861, aged 75, died at his home, March 20, from nephritis

Benjamin F Richards, M D, Pullman, W Va, Lincoln, Neb, Medical College, 1897, aged 81, also a druggist, died at his home, April 27

Robert A Duke, M D, Lake Charles, La, Nashville, Tenn, Medical College, 1866, aged 85, died at his home, March 21, from senile debility

Vincent H Rose, M D, Ladoga, Ind, Rush Medical College, 1869, aged more than 80, died at his home from senile debility, May 8

Hugo Speier, M D, Minneapolis, University of Minnesota, Minneapolis, 1884, aged 65, died in a hospital in Rochester, Minn, May 7

Daniel Harley Kent, Boston, (license, years of practice, Massachusetts), aged 83, died at his home, May 9

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

THE WINE OF CARDUI SUIT

(*Continued from page 1733*)

CROSS-EXAMINATION BY MR HOUGH

TESTIMONY OF DR FRANK BILLINGS (*cont*)

Q —Doctor, you are a member of the A M A, are you? *A* —I am

Q —Are you an officer of it? *A* —Not now

Q —Have you been? *A* —I was President of the American Medical Association in 1902 to 1904 and Treasurer of it, custodial treasurer—I cannot remember exactly how long but I think until 1910

Q —Are you a trustee? *A* —I am not

Q —Have you been? *A* —I have not

Q —Do you read The Journal regularly? *A* —I do

Q —Do you know when they first commenced to attack viburnum prunifolium? *A* —No I do not

Mr T J Scofield —That is objected to It is not cross-examination of anything

The Court —He has answered the question

Mr T J Scofield —All right

Mr Hough *Q* —You are familiar with the working of the Propaganda Department? *A* —You mean of the Council on Chemistry and Pharmacy? I am

Q —You know that it is attacking all proprietary medicines that are sold to the consumer?

Mr T J Scofield —That is objected to

The Court —Objection sustained Dr Billings was not asked anything about the American Medical Association on his direct examination

Mr Hough —I was under the impression that I was entitled to show the environment of the witness for the purpose of determining—

The Court —You may show his connection with the Association

Mr Hough —for the purpose of determining the value of his opinion that he has expressed If he has a prejudice, I am entitled to bring it out

The Court —He has told you that he has read the magazine of the American Medical Association

Mr Hough —I want to find out if he is familiar with the propaganda work and if he endorses the propaganda work?

Mr Walker —May I make a suggestion?

The Court —He may answer the question

Mr T J Scofield —What was the question?

(The pending question was then read)

Mr T J Scofield —There is a false assumption contained in the question

Mr Walker —This is cross-examination, and we have a right to assume things in the question, and the witness can answer as he sees fit

The Court —I think counsel has a right to object on the ground that there is an assumption of fact in the question, that is not in the case

Mr Hough —I think the witness is amply able to take care of himself and if he thinks that I have assumed something in the question that he does not want to include in his answer, he can exclude it

To which ruling of the Court the defendants etc. excepted

A —I do not know that they attack all proprietary and patent medicines The purpose of the Council on Chemistry and Pharmacy is to investigate so-called proprietary and patent medicines ' and after analysis to advise the members of the association and the other readers of The Journal that certain of those proprietary remedies are of value and that certain of them are without value

Mr Hough *Q* —What article do you know of in the Propaganda Department that states that a medicine concerning which it writes is of value?

Mr T J Scofield —I object to that as not cross-examination

The Court —Objection sustained

To which ruling of the Court the plaintiffs etc excepted

Mr Hough *Q* —Have they ever held any proprietary medicine in the Propaganda Department to be valuable?

Mr T J Scofield —I object to that as not being involved here, and not cross-examination

The Court —Objection sustained

Mr Hough —Why, that is brought out by his answer

The Court —No, he stated what the purpose was He stated that the purpose of the Propaganda Department—

Mr Walker —Don't you ordinarily tell what the purpose is the act? And if they have acted directly to the contrary of what he states is the purpose, that refutes his statement as to what the purpose is

The Court —Why, Mr Walker, if you have the magazines here, and want to introduce them you may show what the Propaganda Department has done

Mr Walker —We want an opportunity to show his information about it If he testifies that the purpose is one thing, if your Honor please and the purpose is to inform doctors what are good proprietary medicines and to condemn what they think are bad then sometime in their history they must have been able to endorse some proprietary medicine as good If they never did then the policy of the paper refutes what the witness has said

The Court —The difficulty with the question is that it is not proper cross-examination, and it does not follow at all from the answer given by the witness

Mr Loesch —What are we here for?

Mr Walker —It only goes to the attitude of the witness, that is all

Mr Hough —And usually some latitude is allowed

The Court —You may save the point

To which ruling of the Court the plaintiffs etc. excepted

Mr Hough —What was the last question?

The Court —The last question was, did the witness know of any article in The Journal of the American Medical Association that ever endorsed any proprietary medicine, The objection to that is sustained

The Witness —There are certain—

Mr Hough —Never mind, you are not now asked anything

The Witness —Beg pardon

ATTITUDE TOWARD SECRET PREPARATIONS

Mr Hough *Q* —What is your own attitude towards such medicines offered to the consumer? You are opposed to them, are you not?

Mr T J Scofield —That is objected to

The Court —He may answer that

To which ruling of the Court the defendants etc., excepted

A —Certain proprietary medicines—

Mr Hough *Q* —I am talking about those that are sold to the consumer as distinguished from those which are sold to the doctors to be dispensed on prescription *A* —No I am—

The Court —Just a minute, Mr Hough Are there any medicines that are sold to the consumer that are not sold to the doctors?

Mr Hough —There are medicines called proprietary medicines which are deemed ethical, because they are sold only to the doctors and not to the public

The Court —That was not the question

Mr Hough —Then there are certain—

The Court —Just a moment Your question assumed that there were some medicines that the consumer could buy which the doctor could not buy

Mr Hough —No There are none, of course, which the consumer can buy which the doctor cannot buy Any citizen can buy no matter what his vocation, or profession is, but I am asking the doctor with reference to his attitude about secret proprietary medicines, which are offered to the general public, whether the purchaser is a doctor or a sick woman

Q —What is your attitude toward them, you are opposed to them, aren t you? *A* —Absolutely

Q —Now when you answered the last question—

The Court —Let me interrupt the cross examination long enough to ask the doctor to explain why he is opposed to them *A* —I am opposed to any medicine that is secret

Mr Walker —May we note an exception there.

The Court —Certainly

To which ruling of the Court in propounding his question to the witness as last hereinabove appears the plaintiff etc excepted

The Witness (Continuing) —That is secret in its preparation I will not give myself, nor will I advise anyone else to take remedies the character of which I know nothing about, and a proprietary medicine that is a secret medicine is in a sense a nostrum I not only am opposed to them but I object to them, and I will do anything I could to overcome their influence.

Mr Hough —Doctor you have used Warburg's Tincture in your practice? *A* —Perhaps once or twice in my life

Q —Now you know that Warburg's Tincture was originally a secret formula medicine don t you? *A* —Yes

Q —And you know that Warburg was induced to make the formula public and then he lost the rights which he was entitled to in the medicine, and the profession adopted it, isn't that so? *A* —I do not know that

Q —Haven't you read that? *A* —No

Q —You know nothing about that? *A* —No

Q —Now, in answer to the last question—was that in the same sense in which you would say it would be bad to advise everybody in Chicago to take beefsteak once a day? *A* —No

Q —Not in that sense? *A* —No

Q —Would it be in the sense in which you would say it was bad to advise them to take any particular kind of food three times a day, because the food might agree with some, this particular kind, and disagree with others? *A* —No, not in that sense.

Q —Not in that sense? *A* —No

OXIDIZED ALCOHOL

Q —Now, it is an established fact, or a recognized fact, in your profession, isn't it, that a certain amount of alcohol is freely oxidized in the system, isn't it? *A* —It probably is

Q —And the amount of alcohol which is recognized as freely oxidized in the system is never considered dangerous, is it? *A* —I would not say that

Q —When a person taking alcohol, which has a bad effect, that is because it has not been freely oxidized in the system, isn't it? Not necessarily

Q —What do you understand by being oxidized in the system? *A* —I understand that alcohol may be burned up in the body, oxidized as we say, into carbonic acid and water The carbonic acid is thrown out through the lungs and the water is thrown out through the skin and kidneys, it is no longer alcohol It is burned up

Q —Well, doesn't that mean—I mean, doesn't the term mean that it does not throw any extra burden upon any of the organs? *A* —Not necessarily

Q —Does it in any case? *A* —Yes, sir In that term—alcohol comes under what we call carbohydrates because it is burned up into carbonic acid and water, and the effort of the body to do that may overstrain No one can say—you cannot say it won't be harmful and no one can say in any given individual how much of the alcohol you take is burned up, and how much of it may be converted into fat in his body, or how much of it may be—may go out, and exist in the tissues and irritate them

Q —In other words, you mean that there are exceptions to all rules? *A* —Yes, sir

Q —But the general rule is that there is a certain amount of alcohol which is regarded as being freely oxidized? *A* —That is its natural disposal in the body

Q —Now, when you take forty eight drops of alcohol by itself, is the physiological effect precisely the same as though you took that alcohol with five times the amount of water? *A* —Not exactly When alcohol is taken in a concentrated form, its first effect is to irritate the mucous membrane of the mouth, esophagus, the gullet and the stomach

Q —You are talking now about the 48 drops of alcohol alone? *A* —Yes, I understand the question to be whether it has the same effect, whether concentrated or diluted

Q —That is right. *A* —When concentrated, it will irritate the tissues it touches. That affects the nerves and at once, after the concentrated dose, the heart will go more rapidly for a period of a few minutes and the patient will be flushed and the temperature raised for the time being That is the first effect of concentrated alcohol

If it is diluted, dependent upon its dilution, it will have less irritating effect and, finally, the effect of both will be the same, as it reaches the blood stream and undergoes the change in the liver and in the blood stream which alcohol does But the effect, the physiological effect, would depend upon its dilution

Q —Now, is it not an accepted theory among the profession, that is, among your profession, that up to 20 per cent—that alcohol up to 20 per cent hastens the absorption of the medicines which are in it? *A* —No

Q —Is there a theory on that subject with reference to any per cent of alcohol? *A* —No, not that I know of

Q —Then you would say that alcohol in no per cent hastens the absorption of medicine? *A* —Not necessarily

Q —Does it in any case? *A* —Not that I know of

Q —Are you familiar with the Atwater and Chittenden experiments as to the physiological effect of alcohol?

Mr T J Scofield —Wait a minute, it dont make any difference whether he is familiar with it or not

The Court —He may answer

To which ruling of the Court the defendants, etc , excepted

A —I did not get the question

Mr Hough —Atwater and Chittenden *A* —I am to some degree, I have read both of them

Q —Are you familiar with Cushny's statement on those subjects? *A* —I have not read Cushny's last statement on that

Q —If they should state a contrary opinion, would it affect your opinion? *A* —Not at all

Mr T J Scofield —Wait a moment. I wish to interpose an objection there

Mr Walker —What is the matter with the question?

The Court —Go ahead, Mr Hough

To which ruling of the Court the defendants, etc., excepted

Mr Hough *Q* —You said you had not read Cushny's last statement Have you read any of his other statements? *A* —I read his first work on pharmacology, but I don't remember anything in it concerning that particular thing

Q —You mean the alcohol hastening the absorption of medicine? *A* —Yes

Q —Doctor, what combination of these two drugs named in the hypothetical question, would produce the best physiological results in amenorrhea due to anemia? *A* —What combination?

Q —Yes *A* —I don't know of any combination

Q —In any amounts? *A* —In any amounts

Q —Or in any proportion? *A* —Or in any proportion.

KNOWLEDGE OF CARDUUS BENEDICTUS

Q —Is your knowledge of carduus benedictus based upon your experience with it, or upon your reading about it? *A* —I have no experience with it

Q —Have you any knowledge on the subject at all? *A* —Only as I have read it in the literature of the Chattanooga Medicine Company

Q —Is there anything in the literature of the Chattanooga Medicine Company which says anything about carduus benedictus? *A* —No only as in that combination, as I understood it to exist.

Q —What literature of the Chattanooga Medicine Company said anything about carduus benedictus? *A* —I did not say that it said anything particularly about carduus benedictus, but about Wine of Cardui, which I understand contains carduus benedictus

Q —I asked you what knowledge you had about carduus benedictus? *A* —And I answer that I know nothing practically from my own experience about it That the only literature I have read upon it is in going over the literature of the Chattanooga Medicine Company, about the Wine of Cardui, which I understand contains carduus benedictus

Q —Well, is there any literature of the Chattanooga Medicine Company which mentions carduus benedictus? *A* —I think not

Q —Well, then, you could not have read anything about carduus benedictus in the literature of the Chattanooga Medicine Company, could you, doctor? *A* —Excepting from what I have learned of the testimony here, by reading of the testimony, the analysis of the remedy, which is said to contain carduus benedictus.

Q —Is there any part of the testimony which says that the literature of the Chattanooga Medicine Company mentions carduus benedictus? *A* —In the question, yes, sir

Q —Sir? *A* —The question, yes, sir

Q —I did not understand that. *A* —The question of the attorneys, yes sir

The Court —The hypothetical question

The Witness —The hypothetical question

Mr Hough —I am asking whether the literature—

The Court —He said there was nothing in it, he has answered that twice He said that he assumed from what he had heard that the Wine of Cardui contained carduus benedictus

Mr Hough —I did not so understand the witness, but if the Court understood it that way, we will let it go

Mr T J Scofield —That is what he said

Mr Hough —No, he said he read in the testimony a reference to carduus benedictus in the literature of the Chattanooga Medicine Company, that is what he said

The Witness —I said the testimony given here in this court

Q —Well, then, you mean you have not read anything in the literature of the Chattanooga Medicine Company about carduus benedictus? *A* —Not naming the drug as carduus benedictus

Q —Have you ever read about the drug in any medical literature? *A* —No

Q —Would your opinion as to the therapeutic value of the medicine, based we will say principally upon carduus benedictus be affected by what any medical writer would say about the therapeutic value of carduus benedictus?

Mr T J Scofield —That is objected to if the Court please

The Court —He may answer

To which ruling of the Court the defendants, etc , excepted

A —It would not

Mr Hough *Q* —In other words without knowing anything about carduus benedictus, or having read anything about carduus benedictus, you expressed the opinion that it is utterly worthless as possessing medicinal value? *A* —No, I would not say that. It might have certain tonic properties but as a curative agent of any organic disease, such as I have been interrogated about here today, I would say it is worthless under those conditions

Q —Well, but outside, doctor, of the hypothetical question, if you have had no experience with carduus benedictus, yourself, and have read nothing in medical literature about the experiences of others with it, how can you say what would or would not be its therapeutic value? *A* —Well, because neither that nor any other drug will affect the anatomical conditions about which I have been interrogated in this court

Q —That was not what I asked you, whether it would affect anatomical conditions or not The question is how could you say under those circumstances that the drug did not possess any medicinal or therapeutic value whatever? *A* —I have already qualified it by saying that I did not say that, that I said it might have certain tonic or other qualities of which I know nothing

Q —Will you eliminate from your consideration, for a moment, the statement in the hypothetical question, and answer this question outside of that, as to how you can state what the therapeutic or medicinal value of that drug would be, if you have never read of the experience of others with it, or had no experience yourself with it? *A* —I cannot answer that outside of the hypothetical question

Q —Then you mean that outside of the hypothetical question you could not express any opinion, could you? *A* —I can express an opinion concerning these conditions about which I have been interrogated

Q—I am talking now about the medicinal value or the therapeutic value of carduus benedictus? *A*—No

Q—You could not could you? *A*—No

Q—Now then do you know, for instance how much extractives 20 per cent of alcohol would take from 30 grains of carduus benedictus? *A*—No, sir

Q—Do you know how much extractives a larger amount of alcohol would take from 30 grains of carduus benedictus? *A*—I do not

Q—Do you know whether a larger amount of alcohol would take any more extractives from carduus benedictus than 20 per cent of alcohol? *A*—I do not

Q—Now the hypothetical question is based upon the assumption that the bitter principle is cnicin which is present in approximately one tenth of a grain per dose Would your opinion about the medicine be any different—I am talking now not about anatomical conditions, or its effect upon moving bones but as to the therapeutic value—if the other extractive matter other than the cnicin possessed properties which acted upon the womb and the generative organs of woman? *A*—Do I understand you to ask if the other extractives of carduus benedictus with the exception of cnicin, would—

Q—If they had the reputation of acting upon the womb of a woman, would your opinion as to the value of the medicine be different? *A*—Naturally it would and that would depend too upon what action it had upon the womb necessarily To act, assume—it may be several things

Q—A headache might be due to a menstrual disturbance might it not? *A*—It might yes

Q—If a medicine contained an ingredient which acted upon those conditions it might be a medicine which would relieve the headache that was due to those conditions might it not? *A*—It might palliate or relieve the headache for a time

Q—The word cure is used carelessly by both the laity and the profession or has been in times past, has it not? *A*—I stated that to the jury

Q—I did not hear what you said *A*—I stated that to the jury in my direct testimony

Q—That that is true? *A*—Yes.

Q—Now, there are some conditions of menstrual disturbance or inflammation in the female pelvic cavity which might cause a pain in the back of a woman might there not? *A*—Yes

Q—If a medicine contained an ingredient which had the reputation of acting upon the womb or upon the inflammation of those parts, it might be just the medicine she needed to cure that pain might it not or relieve that pain? *A*—Yes or it might not cure It might palliate. There are remedies which will relieve backache due to pelvic diseases of women which have no effect whatever upon the pelvic disease of itself and so reduce the sensation of the nervous apparatus that the woman has no conception of the ache or pain in her back

Q—Don t you think a woman would usually know whether her headache was due to some female trouble or any of the irregularities of menstruation? *A*—I do not.

Q—You do not think that she would know that? *A*—No

HEADACHE

Q—Could a woman ever know ever have a headache, which she would know the cause of? *A*—Yes

Q—What kind of a headache might she know the cause of? *A*—It is possible that a woman might so suffer knowing by examination that she had pelvic disease, like a retroversion that is a backward displacement of the womb and some other woman if it annoyed her constantly and she was tired out having headaches might have headaches because of the nervous irritation in the pelvis and she might learn to know that.

She might learn that she had a headache because she knew that she had bad eyes, and that the oculist was almost unable to fit her or the eye muscles were unbalanced and he had difficulty in fitting glasses to such an individual and she would know that her headache was due to the constant eye strain human fallibility not permitting her to be entirely fitted with glasses. So that there are conditions in which an individual can know the causes of a headache.

But, take it as a general proposition a woman is not a judge of the cause of the headache any more than a man A man or a woman cannot tell why they have headaches Even we doctors sometimes have difficulty in finding out why an individual has a headache. It takes long study

Q—If a headache in a woman comes regularly every month at her period would she not naturally understand and would not the doctor naturally suppose that it was due to the menstrual period? *A*—Yes but that does not necessarily follow that it is because she has got a disease of the pelvic organs that she has a headache. A woman is naturally more nervous at her menstrual periods, more excitable. The whole nervous apparatus is disturbed and in that very case the headache may become intensified and while she or somebody else might ascribe the headache to the menstruation it is the effect of the fundamental cause.

Q—Is there any medicine which might relieve a headache which was due to a menstrual disturbance? *A*—Yes

Q—And that would be I take it a medicine which the woman would take for the menstrual disturbance? *A*—Yes. Many do

HOME REMEDIES

Q—You said something about a woman during pregnancy taking many simple remedies at her home What kind of remedies did you mean? *A*—Oh simple household remedies She may be nauseated, and she might take a little essence of ginger or she might take a little essence of peppermint or she might apply a little mustard plaster over her stomach for a little while or she has a headache and she has through her family physician some little household remedy which she will take for it She may take a hot foot bath

Q—You have prescribed essence of ginger and peppermint under those conditions? *A*—Why, certainly, if they were—if the conditions needed them

Q—Do you know how much alcohol there was in those essences? *A*—Yes, sir

Q—How much? *A*—Well, the essence of peppermint is an essential oil that requires practically all the alcohol to hold it

Q—A very large amount of alcohol? *A*—Yes, but the essence of peppermint would be taken in a few drops, three or four

Q—How many drops? *Q*—Oh anywhere from three or five or six drops

Q—Frequently? *A*—No, about once or twice a day, or perhaps—and perhaps not again

Q—That is practically all alcohol, isn't it? *A*—Yes.

Q—And in the ginger? *A*—And ginger has also a large quantity of alcohol but the amount of those drugs taken at a time is infinitesimal, and they are not prescribed to be taken three or four times a day so that the total quantity of alcohol, taken by the individual is not much over any given period of time. It makes all the difference in the world whether you are taking alcohol of a certain big dosage or a small dosage, with regularity

Q—Well Doctor what is the largest dose of ginger you have ever prescribed essence of ginger under those conditions? *A*—Oh, usually I just simply use a few drops, because it is usually given for its sense of warmth that it causes in the stomach It has what we call a carminative action that is it stimulates the stomach to move, and the woman will belch gas or if it is in the intestines, they will pass flatus or they are relieved by it It is simply a palliative medicine, given for that purpose

PHYSICIANS PRESCRIBING ALCOHOL

Q—Do you think that alcohol given in a medicine, which a doctor prescribes has any different effect from alcohol which is taken in some home medicine that a person bought without a prescription? *A*—In single doses no but the doctor usually *prescribes* a certain *amount* with directions as to when to take it and when to *stop* The patient that buys his patent medicine' with its alcohol in it takes it of his own volition at any time he choses as much as he choses and as long as he pleases It makes all the difference in the world

Q—Well you could ignore the directions of the doctor or the patient could as well as ignore the directions on the bottle, couldn t he? *A*—He could yes

Q—*Do you know how* many of the pharmacopeial preparations containing alcohol, contain more than 48 *drops of alcohol* per dose? *A*—I do not know just how many of them I know there are a good *many of them* There are some of them contain pure alcohol some of them *contain 80* per cent *75* and 60 per cent You cannot speak of it in percentage It is put in in their making as equal parts of water and equal parts of alcohol, or two parts of alcohol and one of water three parts of alcohol and one of water or four parts of alcohol and one of water and so on so it is not exact percentage

Q—You are talking I think, about percentages I was asking you if you knew how many of the pharmacopeial preparations such as fluid extracts or tinctures contained in a dose, as laid down either in the pharmacopeia or the dispensatory, or the National Formulary, *contain* in a dose more than 48 drops of alcohol *A*—No I do not because it does not interest me. I use *so* few of any of them that I cannot spend the time to look up such a question

Q—You have used cimicifuga haven't *you*? *A*—*Very rarely*

Q—That is the fluidextract? *A*—Yes sir

Q—Well you know that each dose of that contains 57 drops of alcohol don't you? *A*—*I do not know the exact* amount of alcohol it contains but it is a drug that *is very rarely used* When it is used it is not usually used in more than 10 *or* 15 *or* 20 minim doses because it is used in mixtures with other things Therefore while it may contain—

Q—Doctor would you talk a little louder *A*—Although it may contain therefore more than 48 drops in a teaspoonful of it of the simple *drug itself* it is usually used in less dosage than that in *mixtures* and not for any length of time

Q—Did *you* ever use the fluidextract of cinchona? *A*—No sir I do not use it in that form?

Q—In what form do you use it? *A*—I usually use it in the form of a tincture

Q—How much alcohol is there in the tincture? *A*—*That has a* high percentage

Q—That has a higher percentage than the fluidextract hasn't it? *A*—It has I think it has

Q—In a dose of that how many drops of the *alcohol* would a patient get? *A*—Well if you take a teaspoonful *dose I* suppose he would get more than the 48 drops I do not know exactly but again that is not a drug that is used often. It is *only* used sometimes as a so called stomachic tonic that is as a bitter *tonic* for a period and then usually not in its plain dose but with other bitter tonics mixed up and taken as a mixture When we want *long* continued use for the effect of cinchona we use its active principle *quinin* which we can give in powder or capsule or pill having no alcohol whatever

Q—But quinin don t represent all the properties of cinchona does it? *A*—It represents the *most* valuable principle in it.

Q—It represents a *certain* active principle only don t it? *A*—And the most valuable one

Q—Isn t there a difference in medical opinion on that subject? *A*—Not at all

Q—You think not? *A*—No, sir

Q—Why do they ever prescribe cinchona then, instead of just quinin? *A*—Because of its price more than any other thing

Q—Its which? *A*—Price

Q—You mean because it is cheaper? *A*—It is very ineffectual in its effect, as compared with quinin

Q—Is there anything for which cinchona would be prescribed or used, for which quinin would not be used? *A*—No, not that I know of There is one exception I would make to that answer Some people may have uncomfortable symptoms from quinin that are produced by it, like ringing in the ears, and occasionally it makes a hive like eruption on the skin that is a peculiarity of some people in reference to quinin In that event, often, as one cannot overcome it by any other medication, or combination with it, a less effective drug like cinchonidin may be given in its place, but the strength, the comparable strength is very different, but the effect is intended to be the same

Q—Now, when you give a drug which in one dose contains more than 48 drops of alcohol, does that one dose have any bad effect or its deleterious effect? *A*—As a rule, I should say not.

Q—Now, suppose you give that three times a day, and the patient did not take it any more than three times a day, would the second or third dose have any deleterious effect? *A*—I do not know You are asking the question in so general a way that I cannot answer you definitely It would depend on the patient.

Q—Let us take a patient now in whom the 48 drops would be freely oxidized The effect of that alcohol would have passed off before the expiration of three or four hours, would it not? *A*—I cannot assume that I cannot assume that any patient, or any individual, can take 48 drops of alcohol three or four times a day and say that it will be all oxidized or that it won't do any harm, I cannot say that.

Q—Let us take one time only You have given it more than one time, haven't you? *A*—Yes

Q—Now, when you give it one time, it did not have any bad effect, did it? *A*—Not so far as I could say, but I do not know

Q—It did not produce an alcoholic habit, did it? *A*—No

Q—It did not interfere with the action of the drug which you give in it did it? *A*—I cannot conceive of answering that question I don't give a drug of that kind once If I am giving alcohol, I am giving it for a purpose

Q—You mean you are giving it more than once? *A*—Yes, if I was going to give alcohol at all

Q—I am talking about what is going to be the effect of the first dose? *A*—I don't know what the effect of the first dose is I have tried to answer and say here that alcohol acts different on different individuals as to any evil effect or good effect or no effect at all, so far as one can see

Q—When you have given any of these drugs that I have just mentioned to you, and which you said you gave in alcohol, you did not give them for the alcoholic effect did you? *A*—No

Q—You regarded the alcohol as negligible, did you not? *A*—I gave them because it is necessary to have preparations of drugs with alcohol to preserve the drug We have them given to us by our pharmacological manufacturers and our druggists, who put them up for us in that form We prescribe them in that form, disregardful usually of the alcohol in the amount which we give, excepting in that instance where if one prescribes the alcohol, you will be careful of how you are going to give it, just as you would be careful of any other habit forming drug

Q—That is, when you prescribe alcohol as alcohol *A*—No, I said these drugs containing alcohol You would have the same thought in mind

Q—Well, you say that when a drug contains the alcohol which is indicated in the pharmacopeia, it would be regarded by the profession as negligible? *A*—I cannot say what the profession might think

Q—Well, yourself then? *A*—Well, myself, the way I prescribe it, I would say that it would be negligible.

Q—When it came time to take the second dose, would there be in the patient's body any condition due to the alcohol alone? *A*—I cannot answer that question, because I am not around When I prescribe a drug that has got to be taken, it usually means for a day or two days or a week, and I am not around to see what the effect of that drug is on the patient every dose that he has taken

Q—Then you assume, as a matter of course, that where you give a drug containing alcohol in which there would be as much as 48 or more drops per dose, to be taken two or three times a day over a week, that the alcohol would not have any deleterious effect *A*—In the first place, I answer that by saying that I don't prescribe a drug that contains that amount of alcohol that I give a week at a time, and that if I did prescribe it, I probably would satisfy myself that it was not doing any harm on days subsequent to the day on which I prescribed it.

Q—Well, now, when you give a drug that contains alcohol, do you have it in mind to go and see that patient very soon, and see if the alcohol is having any deleterious effect? *A*—I don't take care of any patients, sir, except those that I see daily, except Sunday, and even Sunday—

Q—Would you mind sort of spreading your voice out this way, half way between me and the jury, so that we can both hear? I did not hear the last. *A*—All right, sir My practice of medicine lies entirely, sir, at the Presbyterian Hospital in Chicago, and in consultation with other physicians and in opinions given in the office practice, a few hours a week Consequently all patients that I have under my charge, I see practically every day

Q—But there was a time when you were in the general practice, like a country doctor *A*—No, I never was just like a country doctor

Q—I don't mean like a country doctor, but you would go around and see your patients? *A*—I used to do a large family practice, sir

Q—Of course, then, you saw your patients daily? You did not see your patients daily then, as you do in the hospital, did you? *A*—If they were very ill I did If they were not very ill I some times would not see them once a week But I am quite peculiar, if you will permit me to say that, in that I don't give very many drugs

Q—You mean that is now? *A*—No sir, my patients, many of them, are carried through under a management which does not require the use of drugs often

Q—You mean you differ in that respect from the rank and file of doctors? *A*—I do not know in what I differ from them, I do not know what the opinion or practice of some other men may be.

Q—Then why did you say you were peculiar? *A*—I am peculiar in the sense—you asked me the question whether I gave drugs every day, and whether I watched their effects every day, and if I had a family practice and did not see the patients I could not do it. I say that in many instances I did not give drugs always in such treatment

Q—Well, if all physicians do the same thing, you could not say you were peculiar in that respect? *A*—Well, I will retract the "peculiar" if you want me to

Q—I think that is a good retraction Did you give more drugs when you were in the general practice than since you have been in the hospital practice? *A*—No

Q—When you first started to practice? *A*—No

Q—You never gave any more at any time? *A*—Perhaps when I was younger and without as much experience, I may have had a little more confidence in drugs or confidence in things I would read about drugs than I have now

Q—How long did that condition continue? *A*—Oh, that is a developmental period you know, sir I could not say It has been thirty six years since I began, thirty five

PUBERTY

Q—Did I understand you to say that puberty as a rule is normal, and not pathological? *A*—Yes sir, it is a normal physiological process

Q—Is it not a fact that amenorrhea is common in puberty? *A*—No sir

Q—Did you say that you had heard Dr J Clarence Webster testify? *A*—No sir

Q—Did you read his testimony? *A*—I had that offered to me and read it

Q—Well, don't Dr Clarence Webster say that amenorrhea is common in puberty? *A*—I don't remember

Mr T J Scofield—That question I object to It don't make any difference whether he says it or not

The Court—The witness says he does not know

Mr T J Scofield—But what is the use, your Honor? It is not a proper question

The Court—I do not think it is proper

Mr Hough—What was that?

Mr T J Scofield—Your question, I say, was an improper question

Mr Hough—He said he had read the testimony here, and he said he is associated with Clarence Webster

The Court—No, he said he had been in consultation with him But what difference does it make? Dr Billings has made his statement here and if Dr Webster said something different, apparently they disagree The Jury has heard it

To which ruling of the Court the plaintiffs, etc, excepted

Mr Hough *Q*—Doctor, is your opinion on any subject ever affected by the opinion or influenced by the opinion of any other doctors? *A*—Oh, sure.

Q—Either expressed to you verbally or expressed in some book they wrote on the subject? *A*—Expressed both ways

Q—Well, suppose Dr J Clarence Webster should say that amenorrhea is common in puberty Would that affect your opinion on the subject?

Mr T J Scofield—That is objected to

The Court—He may answer

To which ruling of the Court the defendants etc, excepted

A—It would not affect my—my answer is based on my own experience It does not affect it therefore

AMENORRHEA

Mr Hough *Q*—How many cases of girls at puberty have you had, would you say, roughly, for amenorrhea? *A*—That would be difficult to answer I could not answer that definitely

Q—Well, say in the last ten years? *A*—In ten years I have not done family practice, and therefore I have not seen many, excepting as they would be admitted to the hospital Before that, with a large family practice, helping parents to bring up their children, I saw many girls, and I have seen occasionally amenorrhea, but not a constant thing, and I want to repeat what I said, that when amenorrhea occurs at puberty there is an underlying constitutional condition which prevents the development of puberty, and the word "amenorrhea" should not be used there at all.

Q—What is that? *A*—Its true function is gone

Q—You mean the term "amenorrhea" should not be applied to it? *A*—Amenorrhea is but a symptom and not a condition with a girl It is but a symptom of general conditions, as I reiterated this morning The girl may have tuberculosis, the girl may have an anemia due to a faulty development of the blood her bone marrow may not be acting right. She may have some other constitutional disease, which prevents the appearance of the menses. Every one is alarmed because it is amenorrhea in the girl, when the thing to be alarmed about is her general condition and the amenorrhea don t mean anything That a girl may be a little late in the development of puberty, or that she may be irregular at the beginning is as a rule nothing to be considered as to drugs but as to the correction of habits of life and diet and everything else

Q—Do you define amenorrhea and suppression as the same thing? *A*—Yes practically They are the same thing Amenorrhea means absence of menstruation Suppression of menstruation means absence of menstruation

Q—Suppression means the absence after it has once been established *A*—No, it is simply another word to express the same thing But amenorrhea covers the whole subject of the absence of menstruation

Q—Whether before the establishment or after the establishment of menstruation? *A*—Before or after

Q—Within what time as a rule, is menstruation established in young girls? *A*—On puberty differs in different people and different climates Among the Orientals it is early

Q—I don t mean at what age I mean is it established sometimes immediately right off suddenly? *A*—Sometimes it comes without symptoms at all the girl menstruate

Q—That would be normal? *A*—That would be normal Sometimes it will come with more or less pain dependent on the new function being established

Q—That would not be normal? *A*—It would be in a sense the normal puberty the normal menstruation

Q—Normal in the sense that she must menstruate? *A*—Normal in the sense that she must menstruate and normal in the sense that it is flowing and properly That she may have pain don t indicate that she has got anything wrong about her pelvic organs

Q—It at least indicates that it is not normal doesn t it? *A*—It does not follow that the menstruation is not normal

Q—I don t mean the menstruation— *A*—Or that the puberty is not normal That don t follow at all A girl for instance in our modern life is off at some boarding school and allowed to go into society too much at that early age and her nervous apparatus is irritable with the congestion down here although it is normal that menstruation affects the nerves of her pelvis and she has got pain there when there is not anything the matter with her at all

Q—Garments and corsets would have some effect? *A*—Regardless of everything it don t make any difference She has got pain because of her habits of life and because she does not recognize things that she ought to recognize and she has got pain because of a live battery up here (apparently indicating the head) which recognizes things that it ought not to recognize

Q—That is a condition that requires some sort of treatment doesn t it? *A*—It requires general treatment

Q—Tonic treatment? *A*—To teach parents, for one thing how to take care of their girls and to teach the girls what to do It doesn t necessarily mean medicine

Q—Not necessarily? *A*—Not necessarily

Q—But you would not exclude medicine if it was indicated? *A*—If her condition indicated that she needed something to correct the condition when I found it I would give the proper medicine

Q—And if anemia was one of those conditions— *A*—Anemia was not there. The question was asked me here if the girl had painful menstruation but was menstruating Now if you bring in anemia again, she needs something to restore that blood

Q—Well, I am doing it now When she is nervous and excitable, and has headaches without having anemia all due to the fact that she is not menstruating normally you would not give her any medicine or treatment at all? *A*—I cannot accept that statement If her headache or backache was due to her nerves or is due to the nervous condition—

Q—But I thought you said that was the condition The girl is at school she is wearing tight clothes going out into society or she don t have the fresh air that she ought to have at that period and she has this physiological condition, which you have just described? *A*—The question which I understood to be asked by you was that the girl menstruated but it was painful I tried to say to you that the pain was not necessarily indicative of any disease about her genital organs that she might well have pain with the natural congestion of the womb and ovaries at that period which she would unduly feel because of her nervous irritability due to these extraneous things that I named

Q—Let us get our bearings again Menstruation may be established suddenly and without any pain That is true isn t it? *A*—Yes sir

Q—When that occurs it is normal? That is the way it ought to occur in a state of nature ought it not? *A*—Yes

Q—Now when it don t occur that way, there is a departure from the normal condition without reference to whether it is yet pathological, it is a departure from the normal condition? *A*—It is a departure from what would be considered the normal that would come in a perfect individual without pain

Q—Now then when it is delayed in that way would you or would you not call it amenorrhea? *A*—If it is delayed for the time being no Simply delayed menstruation.

Q—Well in what case would you call it amenorrhea? *A*—When it goes on for month after month without the appearance of having had it regularly month after month suddenly a month drops out and the menses did not appear she had amenorrhea for that month

Q—Of course it is a recognized fact that it don t commence at the same age in every girl? *A*—That is right.

Q—But there is something to indicate in each girl when the time has come for her to menstruate? *A*—Yes.

Q—It is usually a little flow isn t it? *A*—No

Q—What is it? *A*—Usually the development of the other organs of the female The breasts enlarged and she rounds out in form, and her whole aspect is changed and she passes from girlhood into womanhood

Q—Well that would merely indicate that it was about the time? *A*—And then when the menstruation appears, it may be the appearance first of a flow of blood the first that she would know about it

Q—That would indicate the first month when it was due with her, wouldn t it? *A*—On the other hand, it may even with a healthy girl appear—

Q—Did the doctor answer that question?

(The pending question was then read)

A—That would indicate it, yes.

Q—Go ahead excuse the interruption *A*—It might be attended with more or less nervousness, irritability, headache or something of that kind because it is a new thing to her, and Nature has not yet got around to establishing it

Q—Now then, suppose when the month comes around she is irritable in the meantime and has headache would you say that it was then pathological? *A*—No not necessarily

Q—Would you say that it would then require any treatment at all? *A*—Not unless I made an examination of that individual and found out what the true condition was

Q—Now then, suppose the third month comes around and she is still in that condition with some headache would you give her any treatment? *A*—I would *not until I had acquainted myself* with the facts of her condition

Q—Well after you had acquainted yourself with the facts of her condition, what treatment would you give her? *A*—Then I would give the treatment based on those conditions.

Q—We will say now that it is the third month What would be some of the treatment you would give her? *A*—Well it would depend on the cause. Sometimes they are delayed *from general* constitutional things A girl may be housed in school or at home and she may not have enough out-of-door exercise On the other hand she may be a poor girl earning her living in a store or somewhere else and she is overworked and tired physically and mentally She may have faulty methods of life, as to diet and as to bowel movements and one would have to ascertain all *of those facts* and treat the patient accordingly rather than to drive at once at the pelvic organs to find what was the cause

Q—Would you wait three months to ascertain the facts? *A*—I don t wait at all, sir as a rule

Q—Then you would ascertain the fact before the expiration of three months? *A*—I would try to, if the patient were under me, yes sir

Q—How long would you then wait before you would *give her* any medicine? *A*—That would depend on what I found I cannot answer the question because you are assuming a hypothetical girl without my knowing what the matter is with her I cannot answer that question

Q—What conditions did you ever *find in a girl* at puberty which required the giving of medicine? *A*—Anemia, such as I have named is one of the most common causes She either suffers from malnutrition because of faulty habits of eating diet and *exercise* and, all that or her blood making organs are not making blood fast enough and in that event *one corrects* whatever the condition may be

Q—Let us suppose that the condition was *not* due to any malformation or any condition which required a surgical operation *A*—There is sometimes—

Q—There is *sometimes* what? *A*—A malformation

Q—Let us exclude those Suppose the condition which you discovered *her in* was not due to malformation and was not one which required a surgical operation and still the girl dribbled and had *some* pain and had headaches and was irritable and nervous Is that a *condition* which calls for any treatment? *A*—I have already *answered that in saying* that the underlying cause would have to be sought for and removed Those may be numerous I do not know what it may be.

Q—Without reference to the underlying cause could there be any underlying cause which would necessitate any treatment for that *condition of symptoms*? *A*—I have already stated that I would give iron if she had anemia and needed a tonic, or give her some other restorative tonic if iron was not needed If she had tuberculosis, we would treat that.

PREGNANCY

Q—Is it not true that pregnancy in the civilization today is pathological rather than physiological? *A*—No sir only to a certain extent it is a pathological condition

Q—Is that based on your reading or your own *experience*? *A*—On my own experience and reading and association with men whose practice is the care of women who are pregnant

Q—If Dr DeLee should state that pregnancy should be regarded as a pathological condition *would it affect* your opinion? *A*—Yes—or no I would not say it affected it. I believe *that* pregnancy is a normal physiological condition

Q—I say, suppose Dr DeLee said in our present day civilization that it should be regarded as a pathological *condition*? *A*—Does he say that it usually is?

Q—I say suppose he said—I will read it to you if you want me to *A*—I say does he say that it is usually a pathological condition?

Mr T J Scofield—That is objected to

Mr Hough—He says it is

A—Does he say it is usually so? Then I differ with him

Q—You would differ with him? *A*—Yes

Q—Now, have you had in your general practice, before you went into the hospital, many cases of pregnancy? A—As they occurred in the families, I attended a good many

Q—That is where you had a family practice? A—Yes

Q—How • soon, as a rule, would the woman consult you? A—Usually almost at once

Q—You mean as soon as she discovered that she was pregnant? A—Yes sir

Q—Possibly to ascertain from you whether she was or was not pregnant? A—Miss a menstrual period and usually *want to find out* if she was pregnant, or why she had *missed it*

Q—What do you do when a patient consults you under those circumstances? A—When they did consult me under those circumstances, I usually examined them

Q—I mean, when they did A—I examined them *to find out* what the conditions were

Q—Were there any cases of pregnancy in which you ever gave medicine? A—Yes, occasionally

Q—What were the circumstances, the conditions? A—A woman would have disturbed functions It is a common thing for a woman to be constipated, one would naturally attend to that in a woman in pregnancy You always refer them to a diet I said in pregnancy that one of the dangers from which a woman suffers is kidney disease, and so usually when I was a family physician I usually had the pregnant woman, or women, begin to send their urines to me and have them keep it up during the whole pregnancy, so that I could know what the conditions were and then anything that I found wrong with the urine I would correct But there was not any specific thing that one would say that you could give to any pregnant woman It is an individual equation

Q—What other medicines have you ever given in pregnancy? A—Well, I have given iron If I found a woman anemic, I would give iron I have given them medicine to increase the urine outflow I have given them medicines to palliate headache or backache that might be present, in the form of some palliative thing like salicylate of soda, some simple thing, as I have answered before I cannot name any drug that I would say was specific, because the woman was pregnant

Q—Have you never had a case of morning sickness? A—Oh, yes

Q—What do you give in those cases? A—Well, it is a very difficult condition to handle We usually try to give a general management, try to keep the woman quiet if her place in life would permit her to do so, on a light diet Popcorn is one of the best remedies, and a little charcoal, one of the best remedies for a woman who has sour stomach and nausea *when she is pregnant There is not any* specific medication for it.

The further hearing of the case was adjourned until 2 15 o'clock p m the same day, May 4, 1916

Thursday, May 4, 1916, Afternoon

The court met pursuant to recess Dr Frank Billings resumed the stand as a witness in behalf of the defendants

FURTHER CROSS-EXAMINATION BY MR HOUGH

Q—Do you give anything besides popcorn, doctor, in those conditions? A—Yes, carbo lignum, charcoal and small doses, one drop doses, of carbolic acid in water, cinnamon water, any other simple thing

Q—I didn't hear that last What was it? A—Cinnamon water

Q—I have forgotten when you said you quit using viburnum prunifolium in your practice? A—That I had quit?

Q—Have you quit? A—I said that I had used it last during the last year I have therefore used it in recent time

Q—Have you made up your mind to quit? A—No

Q—The last time you used it was on this woman from Texas? A—Yes sir

Q—Whose patient did you say she was? A—She was my patient.

Q—Didn't she come to you from some other doctor? A—I can't recall whether she came with a letter to the hospital or whether he sent her directly there without any word from him, but I have since corresponded with the doctor at her home concerning her She has her physician there

Q—Well, what I meant was, did she have a physician before she came to you? A—She was at one time in the Mercy Hospital under Dr J B Murphy

Q—How long before she came to you? A—She came to me first in July, 1914, and was under Dr Murphy some time in 1913, from her account of herself

Q—That is, she had been under the care of Dr Murphy here in Chicago? A—At the Mercy Hospital

Q—And then she went back home to Texas? A—Yes sir

Q—And then she came back to you? A—Yes

Q—Now do you know whether she had any medical treatment in Texas between the two times? A—Not from my own knowledge, no sir

Q—Did she tell you? Was it part of the history of her case? A—I don't recall

Q—Do you recall what she told you about herself? A—Excepting as to her general condition

Q—Well, did she tell you what treatment she had had previously? A—She told me what treatment she had had in part She said that about three years before she came to me, which would make it 1911, she had an acute rheumatism with inflammation of the tonsils, and the doctors in Texas had taken her tonsils out about three months after she recovered from the rheumatism

Q—That was in 1911? A—Well, she stated—the general term was three years before Then at Mercy Hospital in Chicago Dr Murphy treated her joints with the injection of some material with the object of trying to cure the joints

Q—And how long was she here at that time? A—I don't know that Several weeks—perhaps two or three months

Q—And then she went back home? A—Then she went—as I remember it she went back home and remained during the winter in Texas, and then came north and came into the Presbyterian Hospital in July, 1914

Q—Now, during all that period, or during any part of it, did she have any menstrual disturbance? A—Her menstrual disturbance occurred beginning in 1913, I think At any rate, she had it when she came to me

Mr Walker Doctor, I think you mistook a date there. You said July, 1914 You meant 1915? A—No, July, 1914, she came to me first

Mr Hough Well, she had it in 1913, that is, when she went to Dr Murphy? A—I think she had it then I am not certain, but she gave a description of her symptoms, that she had *painful menstruation* when she came to me

Q—Had she had any treatment for that at all? A—That I don t know

Q—Now, was she cured when she went back after the first trip here? A—No

Q—Did she take any treatment in Texas? A—She took restorative tonics, iron, and at her periods, which were excessive, she was given ergot in the intervals.

Q—That is in Texas? A—That is in Texas. That is as I learned it from her

Q—Did she state she got any relief from those drugs? A—She did not

Q—Did she state during what period of time they were given to her? A—Usually during the menstrual period when she was overflowing, the iron being given between

Q—Being given a few days before and up to the time when it should occur? A—She was given the iron in the interval between because she had poverty of blood, and she was given the ergot, as I understood it, a little before and during the period

Q—And did she continue that treatment until she came up to you? A—I think so

Q—And when she came to you how long did you treat her for those conditions before operating? A—She was under my management for her general condition, which you *will recall* was for general joint trouble, as well as for the anemia and for the pelvic condition, and the attempt was made to improve her general condition and to save her from operation, if possible, by tonics, by ergot, and at that time I tried the viburnum prunifolium

Q—How long was she kept *on that treatment* before the *operation?* A—Well, as I recall it now, it was during about two periods, that is, beginning with one and running through and then over the other period Not all of the time.

Q—About six weeks? A—Not all of the time A part of the time leaving it off, and trying it again

Q—About six weeks? A—Something like six weeks But let me correct that Not continuous six weeks Trying it for the period until it ceased, and then letting her alone, and then giving it again when the flow began.

Q—And did you give her no other medicine between the periods? A—Iron

Q—Only iron? A—Yes.

Q—What other medicines besides the viburnum prunifolium did you give her? A—I gave her ergot

Q—Anything else? A—Not that I recall No specific remedies applied to the hemorrhage

Q—Was the viburnum prunifolium in the fluidextract or tincture form A—In the fluidextract

Q—And the ergot, was that fluidextract or the tincture? A—That was a neutral preparation, ergotol, a part of it, so that it could be given with a hypodermic syringe, and a part of it was the solid extract of ergot given by mouth.

Q—Now for what period of time would you say you gave her the viburnum prunifolium? A—*Probably for seven or eight*, possibly even ten days I can't recall the exact time. While the excessive flow was going

Q—While the excessive flow was going, only through one period? A—No, I then repeated it, as I recall, through a second period

Q—Were you giving any other medicine at the time you were giving her the viburnum? A—I was giving *her the ergot also,* because the viburnum did not apparently *control*

Q—Well, you say the ergot did not control either? A—Nothing controlled in the way of medicines

Q—How many doses, doctor, of the viburnum did you give? A—Three, as I recall it.

Q—And how much at a dose? A—Twenty minims

Q—Twenty minims? A—That is equivalent to about 20 drops not quite

Q—And you didn't try increasing the dose? A—No

Q—And you say you had given it for the previous period *also?* A—I gave it, *as I recall it, for two* periods when she was *flowing* excessively

Q—Doctor, is there difference in the action of drugs when taken in small quantities during a long period of time as compared with large quantities over a short period? A—*Difference in effect?*

Q—Yes sir A—Yes, there may be some difference in effect.

Q—Isn't viburnum prunifolium one of the drugs that is referred to as the kindlier drugs which have to be given over a considerable period of time to get the effect? *A*—I don t know

Q—Don't all the medical writers who recommend it make that statement? *A*—I don t know

Q—You don t know Now you say that you have heard from her When did she go back to Texas? *A*—Went back in September or October

Q—Of 1915? *A*—1915

Q—And do you know what her condition is now? *A*—She was in Chicago in April two or three weeks ago

Q—And what was her condition then? *A*—Excellent, excepting that she has some bony changes in joints, which are as irreparable a if she had been born with stiff fingers

Q—Is she under the care of a doctor now? *A*—She has her own home phy ician and I don t know whether she goes to him regularly now or not

Q—Would you mind giving us her name and address? *A*—I can give you her name I can t give you her address in Texas now Her name is ———————

Q—I mean privately *A*—Oh privately

Q—Yes *A*—I can give you her name and let you know her address

The Court —All that is necessary is to supply it to Mr Hough at your convenience, if you will do so

VICIOUS OR PERNICIOUS

Mr Hough *Q*—Doctor why did you use the word 'vicious' in connection with the recommending of Wine of Cardui during puberty and pregnancy?

Mr Walker — Pernicious I think he said

Mr Hough *Q*—Did you say vicious or pernicious ? *A*—In what connection?

Q—I understood you to say that recommending the taking of Wine of Cardui during the establishment of the menstrual period or during pregnancy or during the menopause I understood you to say was vicious.

Mr Walker —He said pernicious '

A—I think I used the word vicious

Mr Hough —Vicious? *A*—I think I did

Q—I am a little hard of hearing but that is what I thought *A*—Yes And with the purpose in view of giving my opinion that any remedy that is ordered or advised for wholesale use during the puberty during the period of puberty of young women or during the menopause is absolutely wrong probably detrimental to the health of a lot of people and therefore I would call it vicious

Q—Had any one suggested the use of the word vicious to you? *A*—No sir

Q—You had read the article in The Journal? *A*—No, I don t think I have seen that word

Q—You hadn t seen it Well now was it vicious on—first is the opinion that a thing is vicious a medical opinion or an ethical opinion? *A*—Why I would say an opinion as a humanitarian

Q—But not as a medical opinion? *A*—As a medical opinion—as a qualified medical opinion yes

Q—Now does that opinion presuppose that the drugs in the medicine are absolutely inert and worthless? *A*—No

Q—Is that based on the opinion that the drugs have some potency? *A*—I would be willing to assume that they had some potency

Q—Well do you know whether those drugs in that quantity have potency or not? *A*—In the hypothetical question it was stated that they were present in as I understood it amount to physiologic effects but in a small dose and I would say that the use of any remedies advised generally for the use of women suffering whether in puberty or any other time — it don t make any difference what the drugs — I don t care what they are—is wrong

Q—Well doctor assuming that the hypothetical medicine is Wine of Cardui have you an opinion whether or not it is a potent medicine apart from the alcohol? *A*—Upon the assumption included in the hypothetical question—

Q—Either on that assumption or based on your own knowledge? *A*—And it was stated in that hypothetical question that the drugs named in it were practically Wine of Cardui as I understood it.

Q—Well now assume that they were Wine of Cardui *A*—And I was given to understand that the physiologic effect of those drugs as named there were certain things—a certain sedative effect on the spinal cord from the viburnum a certain sedative effect on the organs in the pelvis that the other ingredient the carduus benedictus had a bitter principle a certain bitter tonic principle Therefore as far as those things go they have a medicinal effect.

Q—What would be the medicinal effect of the hypothetical medicine? *A*—Just what is stated in the hypothetical question

Q—Well what would be the effect, so far as the medicine itself is concerned—and eliminating the alcohol as having any effect—on a woman who had amenorrhea? *A*—I don t think it would have any

Q—On a woman who has menorrhagia? *A*—I don t think it would have any

Q—On a woman that has metrorrhagia? *A*—I don t think it would have any

Q—On a girl or a woman who has dysmenorrhea? *A*—It is a possibility that, given enough of it that it might have enough sedative effect on the spinal cord and with the alcohol in it, to relieve the pain

Q—I am eliminating the alcohol so far as the physiological effect is concerned *A*—As far as the physiological effect is concerned it is assumed in that question that it had an effect on the spinal cord The spinal cord is the path through which pains and other sensations pass to the brain so that a woman may recognize them If it had a sedative enough effect on the spinal cord to interrupt those impulses, or the knowledge of pain, it would relieve the pain

Q—Would it have any effect on a girl in puberty where the establishment of a menstrual period was with some difficulty *A*—I think not

Q—And suppose she had pain in connection with the establishment of the period? *A*—The same answer would apply to a dysmenorrhea or painful menstruation that it is possible that the drug named, having a sedative effect on the spinal cord, might palliate pain

Q—Now is your opinion with reference to the bad effect of giving it at such time based on the effect which you expected the medicine to exert apart from the alcohol, or based on the effect which you understood or thought the alcohol itself would effect or have? *A*—First of all I would consider that the alcohol given in that amount to a young girl right along would be harmful at least with certain individuals as I explained about the use of alcohol If used over a long time in puberty, which may be a long period in a girl s life it may extend from the quick establishment of it to the development over three or four years of time before that girl is rounded out into her full womanhood and during that period she might be irregular and to take that amount of alcohol steadily over a long period of time might establish a habit of alcoholism And certainly in the amount given one cannot say how much irritant effect that would have on the tissues of that girl's body to do her harm As far as the other medicinal ingredients are concerned—that is a part of the question—I don t think they would have any effect in establishing menstruation

Q—Would it have any effect on her at all? *A*—It might have some sedative effect as I have explained

Q—Would it have any deleterious effect on her at all? *A*—That I can't answer I would say this that any drugging it don t make any difference if the remedies were not potent were not harmful—to think of an individual taking the drugs along three or four times a day week after week and month after month, as would be necessary in certain conditions of the development of a girl would be harmful. A bad habit established looking to drugs for help, even when they had no effect at all

Q—Well if they were inert it would be no more harm than taking water? *A*—No, but it would be taking drugs just the same

Q—You mean so far as name is concerned? *A*—It is a bad habit.

Q—Well would there be any other physiological effect except the habit of taking something which was called a drug? *A*—I can only assume the physiologic effect named in the question and if the drugs have that effect they would continue to have that effect physiologically

Q—You mean the sedative effect? *A*—The sedative effect, unless long continued use of it habitual use of it it would finally lose that effect, not react on the individual who was taking it.

Q—Now which do you think is the greatest danger to the girl the effect of the drug that is in the hypothetical medicine or the effect of the alcohol in which it is given? *A*—I think the alcohol would be the more harmful thing but as the two were given together that was beside the question That is they are given together and any harmful effect must be the total bad effect of the whole thing

Q—Well now neither carduus benedictus nor viburnum prunifolium is regarded as a habit forming drug? *A*—No

Q—So that if there is no deleterious effect from the alcohol there would not be any serious, objectionable or deleterious effect in giving the medicine would there? *A*—Yes but there will be an ill effect from the alcohol

Q—From 48 drops in five times that amount of water three times a day? *A*—Given indiscriminately and over—

Q—Well I am asking taking it just three times a day for five days and then stop *A*—Probably not

Q—And then if it was given at the next period three times a day for five days and then stopped would there be any deleterious effect? *A*—I think not Maybe or may not But—

Mr Hough —That is all Thank you

REDIRECT-EXAMINATION BY MR T J SCOFIELD

Q—Doctor just one or two questions. Now in speaking of the effect of viburnum prunifolium and carduus benedictus in this medicine Mr Hough asked you as to its sedative effect. The hypothetical question which I put to you concedes a sedative effect when the medicine is given in from 30 to 60 grains or a full dose Now when you answered as to the sedative effect you had reference to the full doses I assume did you? *A*—I did

Q—Yes sir And not to the amount of the medicine approximately 3 grains contained in the hypothetical question? Is that right, doctor? *A*—That is right.

Q—Now if 30 to 60 grains was required in order to produce a sedative effect would there be any sedative effect—how much of a sedative effect do you think there would be if taken in the extractives from 3 grains? *A*—There may be a sedative effect proportional to the dose of course

Q—Doctor Mr Hough has asked you if a medicine which contains carduus benedictus contained extractives other than cnicin which were active on the womb whether or not it might be effective And you answered that in the affirmative Now doctor assume without knowing what those other extractives might be, assume doctor that a woman s abdomen should be opened and her uterus should be exposed—

Mr Hough —I object to this as improper cross That is direct examination

The Court —Let him finish the question, Mr Hough

Mr Hough —All right I know what he is going to say

The Court —Yes Let him finish

Mr Hough —All right, finish the question

Mr T J Scofield —Shall I go ahead with the witness, your Honor?

The Court —You may ask the question for the record, but it is not redirect-examination It does not cover anything that the cross-examination brought out

Mr T J Scofield —I think it is, if the Court please

The Court —Let him ask the question

Mr T J Scofield —And I will state why

The Court —Finish your question

Mr T J Scofield —I will finish the question

Q (continuing)—And there should be injected into the uterus 45 grains of this preparation containing the extractives that Mr Hough interrogated you concerning, and that as a result of the injection of that quantity of the solution into the uterus there was not, within the space of ten minutes, any action of contraction or relaxation whatever Now what would you say as to whether or not the extractives of cnicus benedictus was a tonic, or produced a tonic effect on the uterus?

Mr Hough —Now that is objected to

The Court —I will let him answer on the theory that it was overlooked on the direct examination

Mr Hough —Very well Very well

Mr T J Scofield —We didn't ask him anything about cnicus benedictus

Mr Hough —If it was overlooked, let him answer

Mr T J Scofield *Q* —Answer the question, doctor *A* —I should say that would indicate that the extractives, or that the virtues of the medicine were not tonic, would not contract the uterus and would not contract the blood vessels

Q —Well suppose that under similar circumstances there was nothing to indicate any sedative effect on the uterus *A* —Inasmuch as I understood in the question that no relaxation occurred, that would indicate that there was no sedative effect

Q —Now, doctor, Mr Hough also asked you about the condition of pregnancy, and as to whether or not it was a pathological condition, or frequently so, and he also asked you whether or not your own opinion would be influenced on that proposition by the opinion of others Now what have you to say about that, explaining fully your views on that subject? *A* —I said before that I considered pregnancy a physiologic, normal condition That there were a few exceptions, anywhere from 4 to 10 per cent, in which women developed some disease as a result of pregnancy, and I named Bright's disease, the wrong implantation of the after birth, and other things. Now there are other conditions that occur that perhaps would make one state that pregnancy was an abnormal condition, or had symptoms connected with it, that is due to the fact that the woman before she became pregnant, and while she is pregnant, is suffering from a constitutional disease A woman can suffer from tuberculosis, from malaria, from hookworm disease, from typhoid fever, from other things while she is pregnant, and even with these more chronic things like malaria and hookworm disease and tuberculosis which have existed for months, perhaps years before she became pregnant. Now she is an ill woman She is bodily ill, she is suffering from malaria She is suffering from hookworm disease She is suffering from tuberculosis. And she doesn't feel well while she is pregnant, and she may have some abnormal things develop in that pregnancy because she, herself, is not well Now that occurs to a large extent in some parts of our country Those who have been qualified to make the surveys show that there is about 21 per cent. of malaria carriers in the south in Tennessee, and in Mississippi, Louisiana and Texas, and through the malarial districts, 20 per cent of the population are malarial carriers In Kentucky and in the South beyond that there are something like 30, 33 to 35 per cent. of hookworm sufferers among women and men You know how prevalent tuberculosis is with us everywhere. And women have those diseases as well as men, and the women become pregnant while they are in that condition Now that is not a pathological pregnancy, that is a pathological individual who has become pregnant, and suffers in consequence And the remedy given for any symptoms that she suffers from during that pregnancy has got to be applied to the condition which makes her ill while she is pregnant She will remain ill as long as she carries hookworm, she will remain ill as long as she has got malaria, she will be more or less ill during her pregnancy if she suffers from tuberculosis, which you cannot remove

Mr T J Scofield —I think that is all, doctor

RECROSS-EXAMINATION BY MR HOUGH

Q —Doctor, while pregnancy, of course, is not a pathological condition, most women who are pregnant have a pathological condition, don't they? *A* —You asked me that question, sir, and asked me if it was not usually a pathological condition

Q —Well, but I didn't mean to indicate that pregnancy itself was a pathological condition *A* —I so understood it

Q —No, I mean whether the woman has not usually a pathological condition while she is pregnant? *A* —No

Q —Never? *A* —Oh, I have already answered that, that in certain places in the country there are 20 to 33 per cent of the women that are probably ill, but in our great Northwest and through here, with the 9,000,000 nearly of farmers all over this country, the women bear and they do not need a doctor half of the time

Q —Of course in that condition it would not be pathological?

A —Naturally it is not pathological

Q —Now, in referring to that district, isn't all you could say about that, that that medicine did not act in that case? That would not prove that that medicine would not act in any case, would it? *A* —Not at all

Mr Hough —That is all

Mr T J Scofield —That is all

The Court *Q* —Dr Billings, you said with reference to reaching the age of puberty that if the menstrual flow established itself at once it was normal Now do you mean by that that in an instant, or over night the girl becomes a normal, grown woman, or does it begin with the small flow, increasing as the period goes on, and gradually becoming normal? And over what time would you regard the maturity of the girl established, generally speaking? *A* —Generally speaking, we speak of puberty as a period when the girl changes to womanhood In some girls that may be rapid, in the change A girl takes on all of the characteristics of a woman in her breasts, and menstruates, menstruates regularly It is normal for that girl

Mr Hough —You mean right from the start?

The Court —What I wanted was—

The Witness —Now the other girl, just as healthy as that one, will take one year, two years, three years for that womanly development. It is an individual characteristic It is a familiar characteristic. She may menstruate in that two or three years a half a dozen times, she may menstruate twenty times, she may menstruate regularly It doesn't make any difference If she is normal she may have that whole period of development. Now she may have at any time pain, as I have explained to you, because of certain general conditions, because of her environment, of her parentage, of what her surroundings are at home, and what she is doing We have girls go out here at early puberty, working as cash girls in stores, they are working their heads off, they get bad air, they do not get the proper rest, they may have pain, but that girl is a normal girl It may be she has got no menstruation, but she is just as normal as the girl that lives on Lake Shore Drive

The Court —What I wanted to get at was whether your experience would give any average time from the beginning of the change to the end, the normal beginning to the normal end? *A* —The normal end of menstruation?

The Court —No the change *A* —One can only say that it may—

Mr Hough —I think the Court means the establishment of menstruation

The Court —Yes.

The Witness —Yes That may be anywhere from two or three months, or a month, as we would say that begin suddenly, or two or three years or four years That is the state of puberty, and the menstrual period is not necessarily an index that that girl's sexual organs are not developing properly That girl, getting married even in that state of puberty, when she may be irregular, is able to conceive although she is not menstruating

Mr Hough *Q* —But the normal condition, doctor, in a state of nature, means that as soon as a girl starts to menstruate she menstruates completely? *A* —Yes, but when you say normal you can hardly use the word as a unit to compare everybody with There are people that say that none of us are normal mentally, not one of us. That we do not find the perfect individual So when you say a normal menstruating girl, a girl at puberty, who are you going to set up for the normal?

NUBILITY

Mr Hough *Q* —Just before you get off the stand, doctor, will you explain to the jury the difference between puberty and nubility? *A* —And what?

Q —The difference between puberty and nubility? *A* —I don't get your his word.

Q —Nubility *A* —Nubility?

Q —Nubility? *A* —Nubility, you've got me

TESTIMONY OF DR. H L APPLETON

Dr H L. Appleton was called as a witness for the defendants

DIRECT EXAMINATION BY MR LOESCH

Dr H L Appleton testified that he resides in Gadsden, Ala, and has been a practicing physician for about twenty-four years He graduated from Vanderbilt University in 1892 He went to Cedar Bluff, Ala, where he practiced eight years, then to Center, Ala, and next to Gadsden He is familiar with the use of Wine of Cardui The first case which he described was that of Mrs A

A —Mistress A, age 26, married, one child The family history negative She called on me in the spring of 1909 for consultation I asked for an examination, after going over her family history, and she refused, but returned, and the examination was made the next day, as I remember it I found a mass in the lower abdomen which seemed to be about the size of a pint, or between a pint and a quart cup She was complaining of headache, pain in her back and legs, and scanty menstruation After getting the history as carefully as I could I advised an operation, which was refused, and she returned to her mountain home, which was about 18 miles from our town In the fall of the same year I got a phone message to go out on Alabama street, and I found it was the same patient Her condition was worse I found her in bed She claimed to have had a chill, but I found no temperature I went over the case carefully, and made the bimanual examination I found the mass had grown larger and her condition was worse I asked her why she had not returned sooner, and she said that she had been advised by her friends, and reading of advertisements to try Wine of Cardui for her relief She did so as directed on the bottle She kept it up until I was called in I asked her if it had done her any good She said she did not think so because she had grown worse as she thought all the while I again advised the operation, which she consented to after consulting her family and removed a dermoid cyst—to my recollection it was from the right ovary the right side, and a part of the left ovary was left I removed the tube and part of the left ovary To-day as far as I know, she is alive and well

Mr Loesch *Q*—How long was it between the time of the operation and the preceding time that you had seen her? *A*—I don t quite understand you

Q—How long a time had elapsed between the time you saw her when the operation was performed and the preceding time? *A*—To my recollection it was just about five months

Q—About five months? *A*—Yes sir

Q—And during that time she stated she had used Wine of Cardui? *A*—She had used Wine of Cardui

Q—Did the history indicate that she had used it previous to that time? *A*—She gave no history of that time just between those times

Q—Was the dermoid cyst that you removed similar to the one that Dr McKenna showed here? *A*—There was no bone in mine I don t remember whether he showed—

Q—There was no bone in yours? *A*—No, mine was just a brown *curly hair—a whisp*

Q—What is your next case, doctor? *A*—Number 2 a girl 13—she gave her age from 13 to 15 She was not positive nor neither was her mother, as to her age She was the daughter of what we call a woodchopper

Q—A woodchopper *A*—Yes sir a woodchopper, and making my rounds I was called in to see her in a convulsion I relieved the convulsion as readily as I could and made an examination and found her with a high temperature quick pulse and very tender over the abdomen I asked her for an examination, bimanual examination which was consented to and I found an imperforated hymen I punctured that and I suppose there was about a pint of pus or a fluid with a very bad odor to it about the consistency—it looked like coffee grounds something to that effect as near as I can state I found after passing my finger in, following up the canal as far as I could that it was a contracted canal of the vagina I dilated that with what is known as a vaginal speculum, or virgin speculum washed it out with a normal salt solution hot water, and left some bromid with instructions for her to be brought to town for further treatment as early as possible She gave a history of never having menstruated having had pains for two or three years from as her mother expressed the blood flowing to her head, and that was what she laid to the cause of the convulsions. And I asked her what she had been doing and she said he had been using among other things Wine of Cardui I asked her for how long She said for some—about eighteen months And I asked her how long it had been since she took the last of it if she had a bottle of it in the house No she said she hadn t had any, she said she had got a bottle of Wine of Cardui that her husband traded a rattlesnake for And I suppose that was about two months before that he was in town

It was brought out that the father of the patient traded a rattlesnake for a bottle of Wine of Cardui.

The next patient was Mrs S

A—Mistress S told me to see her in a case of hemorrhage she was having a severe hemorrhage She was nervous anemic yellow in color cast and upon a bimanual examination I found the vagina almost filled with a cauliflower formation The odor was very bad She was suffering with pains in the head and back her extremities and the lower bowel. I advised an operation, and the family refused She passed from under my care and about four or five months later I was called back to the same patient at the same place, for the treatment for the controlling of another hemorrhage which was more profuse than the one previous I still insisted on the operation and asked her why she had not had something done sooner I told the family that she was beyond my reach as I considered it She said that she had relied on the use of Wine of Cardui to relieve the symptom that she complained of so she had taken it according to the directions on the bottles for two or three bottles I don t remember just which and then increased it, but got no results They consented to consultation and she was carried to Birmingham to the South Highland Infirmary and what is known as the ——— operation was done by Dr Prince at Birmingham As far as I know she is alive to-day We only promised her from one to three years of relief

This patient was operated on later in the same year The next patient was Mrs B

A—Mistress B aged 30 married Called to see her in 1914 Found her in bed pale nervous severe cough, complained of headache scanty menstruation had occasionally high temperature had a hectic flush When asking for an examination she refused She said that she did not send for me to treat her medicinally She only wanted me to treat her for the Wine of Cardui—for laudanum habit which she had gotten into She asked me to keep—she said her husband knew nothing of her condition and did not want him to know and she knew she could *not* live long and wanted to die sober I told her I would *do the best* I could for her I put her on treatment and advised her to leave off the laudanum and the Wine of Cardui which she promised to do and she went on and died

Q—*Now did she state to you how long she had been using the* Wine of Cardui? *A*—About a year and a half

Q—Did she state how long she had been using it before she used the laudanum with it? *A*—No, sir she was trying to reduce the Wine of Cardui, that is how come it she got into the habit of laudanum

Q—She claimed she reduced to one bottle a week with the use of the laudanum? *A*—Yes I asked her how she managed to get it She said it was bought by a neighbor for her

Q—What year was that doctor? *A*—That was in 1912 1913 That *was in an adjoining county*

The witness testified that his driver, a man named W N would drink Wine of Cardui as a beverage when he could not get whisky A woman named S H he also saw drink Wine of Cardui as a beverage He also saw a young man named W W drink Wine of Cardui as a beverage

Mr Loesch *Q*—What year was that? *A*—That was 1906 He came in the drug store and asked for a bottle of Peruna I told him I didn t have it *Then he asked for alcohol and I told him I couldn t* let him have it as he was a chronic alcohol—

Mr Walker—I object to that

The Court—Yes, strike that out What we want to know is, did you see him drink the Cardui

Mr Loesch *Q*—Yes

The Court—Strike out everything after he said he came into the drug store

The Witness—He split a bottle with a friend of his and they drank it there in the drug store and I have another case, Mr P——, a printer

He also saw S P drink Wine of Cardui out of the bottle

CROSS-EXAMINATION BY MR. WALKER

The witness testified that he left Alabama on the 27th day of March, that he has been in Southern Illinois part of the time, and that he went to Southern Illinois at his own expense

Mr Walker *Q*—Do you know how you were found to have any information?

The Court *Q*—How did you happen to come up here, that is what we want to know

The Witness—Well Judge I bought a ticket and came up on the—

The Court—How did you happen to come *A*—I came as a witness for the American Medical Association

The Court—We want to know who asked you, and what were the circumstances

The Witness *A*—Well I got a letter from Dr Heizer

The Court—I want facts

The Witness *A*—I paid no attention to the first letter, and I got the second one asking me to meet him at the Detweiler Hotel in Birmingham Alabama

Q—Yes Do you know how Mr Heizer got your name? *A*—I do not

Q—Or how he happened to write to you? *A*—I do not

Q—Have you got a copy of the letter that he wrote you, the first time, with you? *A*—No sir, unfortunately my grip was went in o and I lost it

Q—Was Heizer with you on that occasion? *A*—No sir there was nobody with me when it was done.

Q—When did you get the second letter from Mr Heizer? *A*—It *was some time in 14 or*—

Q—What? *A*—Some time in 1915 I don't remember the exact date

Q—Can you give us the date when you got the first one? *A*—No sir I didn t pay any attention to the first one

Q—You didn't *pay any attention to that one?* *A*—*I beg your* pardon?

Q—How much time elapsed between that one and the second letter? *A*—I couldn t tell you

Q—Where did you first meet him? *A*—I met him at Birmingham the Detweiler Hotel

Q—Did you go there in response to the letter? *A*—My recollection is he asked me to meet him at my office or in Birmingham and I replied—I think it was by wire though—I replied that I had to be in Birmingham, and I would meet him there

Q—Now then did you give him on that occasion in Birmingham these names that you have testified about here? *A*—No sir

Q—Of these persons? *A*—No sir not all of them

Q—Did you give any of them? *A*—Part of them

Q—Were you then asked by him to look up other cases where people had drank Wine of Cardui? *A*—I was not.

Q—Do you know Dr Goddard? *A*—Dr who?

Q—Dr Goddard *A*—I know of him

Q—You and Dr Goddard had been together while you have been in town? *A*—Considerably so yes sir

Q—And at the same hotel? *A*—Yes sir under the supervision of a detective *most of the* time I think.

Q—Yes?

Mr Loesch—And pursued by detectives most of the time? *A*—Under the supervision

Mr Walker —I don't wonder that they had you watched

The Witness —I am not sure—

Mr Loesch —It is about time that the jury finds out they are all watched

Mr Walker —I don't know why you should hire men to watch your witnesses, but I am sure that you may if you want to

Mr Loesch —I don't know who is doing it, but I know we are all watched And I know that I am not having myself watched

The Witness —It was not at my solicitation that I was watched

Mr Loesch —It is not at my solicitation that I am being watched, either

Mr Walker —It might be better if you would do that

Mr Loesch —It might be, that might very well be

Mr Walker —Now I apologize for their putting detectives on to you

The Witness —Oh, there is no apology necessary at all

The witness was then cross-examined concerning S P He stated that S P drank part of the contents of the bottle and put the bottle in his pocket the first time the witness saw him drink it He testified that he sold to S P a part of the Wine of Cardui which the latter drank He was cross-examined concerning each occasion when S P drank Wine of Cardui The witness testified that he himself has not drunk Wine of Cardui, but he is not a prohibitionist

The witness testified that S H, W W, S P and W N are all dead

Q —W N —the driver that drove for you? The man that used to stop the rig and get out and take a drink when he was driving you who would stop and get out and take a drink of Wine of Cardui, and then get in and drive you to the next place *A* —He never had a family, so far as I know

Q —Didn't he use to take a bottle of Cardui, when he was driving, and take a drink, and then go a little further along with you, and then take another drink of Cardui out of his bottle? *A* —Yes, sir

Q —Did he drive you every day? *A* —No, not every day

Q —Over how many years did W work for you? *A* —Two years

Q —Two years? *A* —Yes, sir

Q —Was it a buggy or a horse or an automobile that he drove? *A* —Well, sometimes one horse and sometimes two horses

Q —Would he drink more Cardui when he was driving two horses than he did when he drove one? *A* —Well, I did not take any notice of that

Q —Well, did you sell W N this Cardui? *A* —I beg your pardon?

Q —Did you sell him the Cardui? *A* —No, sir

Q —Did he use to get it from your drug store? *A* —Sometimes Sometimes in the country store

Q —Stop on the way, when you were driving somewhere? *A* —Yes, sir

Q —And get out and get a bottle? *A* —Yes, sir

Q —And come back and get in and drive you along again? *A* —That is correct

Q —Didn't you make any objection to his buying the Cardui from the country drug store, instead of buying it at yours? *A* —I did not

Q —Where was your store when W N was alive? *A* —It was at Cedar Bluff, Alabama

Q —The same place, Cedar Bluff? *A* —Yes

Q —Did he die while he was still in your employ? *A* —No, sir

Q —How long after he quit you did he die? *A* —I could not tell you

Q —When did you last hear of him? *A* —Oh, 19—, somewhere in 1900

Q —Where was he then? *A* —He was at Cedar Bluff

Q —The same place? *A* —Yes, sir

Q —Was he married or single? *A* —He was single

Q —Now, your first experience, as I remember it, ever seeing any body drink it, was in 1894

Mr Hough —'93

Mr Walker —'93 the first? Is that right? *A* —That is right, 1893

Q —W N was the first one? *A* —Yes

Q —Now, that is 23 years ago Well, will you name any human being in any place that you have ever lived in the last 23 years that you ever saw take Cardui as a beverage, that is, alive, or who has a relative alive, that you can tell us of, and give us his name and address? *A* —I don't know that I can

Q —These four dead ones are all that you ever saw drink it, are they not? These four dead ones are all you ever saw take it? *A* —All I call to [illegible] just *now*

Q —Is your compensation here in Chicago based at all on the number of dead ones you can testify about?

Mr Loesch —I object to that

Mr Walker —I am just asking him if it is a fact

Mr T J Scofield —That is not a proper question

The Court —That is not the way to get at it, Mr Walker

Mr Walker —All right

Mr Loesch —If you want to make fun of it, that is a little different

Mr Walker —He is not at all amusing to me

Mr Loesch —It must be very amusing

The witness then stated that he would give to the attorneys for the plaintiff the names of the women to whom he referred, also the names of their husbands and addresses, so far as he is able He was then cross-examined concerning the case of Mrs A and the case of the woodchopper's daughter He answered in detail questions concerning the various examinations and the pathologic conditions found in these cases He also gave the names of the physicians who performed the operations on these cases

The witness was then questioned in detail concerning the case of Mrs B He gave her strychnin as a tonic and advised a diet This patient had tuberculosis but did not wish to be cured of the tuberculosis, she wanted to be cured of the laudanum and Wine of Cardui habit The witness last saw her husband in 1913

TESTIMONY OF DR. JAMES W FENNELL

Dr James W Fennell was called as a witness on behalf of the defendants

DIRECT EXAMINATION BY MR LOESCH

Dr James W Fennell testified that he is a physician residing in Landersville, Ala He graduated from Birmingham Medical College in 1901, and has been practicing in Landersville since that time He was called to see a Mrs E W at night and found that she had taken about two thirds of a bottle of Wine of Cardui The patient feared a miscarriage She had been taking the Wine of Cardui for three or four weeks off and on and that day had secured a fresh bottle, of which she had taken about two thirds He stated that she was disgustingly drunk. She was a woman about 25 or 26 years of age He treated her in 1906

Another case was that of Mrs B He examined her and found that she was pale and anemic She gave a history of amenorrhea, for which she had been taking Wine of Cardui She had had a miscarriage the year before and had been attended by an old negro woman The abdomen was distended similar to the condition in pregnancy On examination he found the cervix completely closed He called consultation, the cervix was opened up and perhaps a gallon of an offensive semifluid mass passed off The patient promptly recovered This case was seen in 1907 The patient had been using Wine of Cardui five or six months

Dr Fennell was called in consultation to see Mrs S, who had been suffering with pelvic pains for nearly a year, and had been taking Wine of Cardui without improvement Her family physician told her she had cancer On examination Dr Fennell found she had cancer, which was too far advanced for operation The patient was a woman between 45 and 50 years of age She had children and grandchildren The patient died This case was seen in 1910

Mrs J H consulted Dr Fennell in 1902 She was about three months pregnant and had had four miscarriages previous to that time The previous pregnancies had not gone longer than the fifth month The patient had been taking Wine of Cardui each time Dr Fennell forbade the Wine of Cardui, put the patient under treatment, and she went the full term, and has had four or five children since that time The patient stated that she had used the Wine of Cardui to prevent miscarriages

The witness was called to see Mrs P B, who suffered with profuse menstruation and hemorrhages She was weak and had been taking Wine of Cardui for five or six months without relief On examination he found that she had pellagra from which she died in an insane asylum She was about 27 years of age, and had been using Wine of Cardui for five or six months

Miss M F was an orphan girl 27 years of age, suffering with amenorrhea, who had been taking Wine of Cardui off and on for years She took it when she could get money to buy it She was pale and anemic On examination he discovered she had hookworm for which she was treated and recovered

Mrs A L B he saw in 1912 She had profuse menstruation with hemorrhages On one occasion when she fainted Dr Fennell was called She had been taking Wine of Cardui to correct this condition for seven or eight months Dr Fennell stopped the Wine of Cardui and the patient recovered under treatment

The next case was Mrs C F She was having convulsions when Dr Fennell was called Labor had started and the convulsions were those of puerperal eclampsia The feet and legs of the patient were swollen He found that she had been taking Wine of Cardui On examination of the urine it was found to contain albumin Dr Fennell and another physician treated the patient for several days She became well The mother and baby both lived She had been taking Wine of Cardui about six months

Mrs H S, 38 years old, also had puerperal eclampsia convulsions, albuminorrhea and swelling of the feet and limbs Dr Fennell saw her in 1903 at the termination of the pregnancy The patient was saved, but the child died It had been dead for two or three days according to the opinion of the physicians

Mrs B C, a colored woman, Dr Fennell saw in 1910 She had been suffering with convulsions due to eclampsia She had been taking Wine of Cardui for four or five months Both mother and baby recovered under treatment

Dr Fennell was then asked to describe any cases in his knowledge in which Wine of Cardui had been used as a beverage. In 1904 a man brought his wife to consult Dr Fennell They gave the history that she had been suffering with a run down feeling She decided she had female trouble and had taken Wine of Cardui At first it seemed to help or relieve her Later she doubled the dose and finally began to take a third of a bottle at a dose twice a day

Mr Loesch *Q*—Did she come to you for treatment for alcoholism? *A*—She did not know what it was Yes she came to me for treatment for whatever was in that Wine of Cardui

Q—That is it Now tell what you did there *A*—And she stated after she got her dose that morning she and her husband were going to church and she was not able to go but he told her they would stop up here and see if they could get a tonic She got there and opened the bottle and took two or three doses before it had the desired effect And then it had such an exhilarating effect it made her so talkative that it aroused her husband s curiosity, and they got talking over it and they decided—

Mr Walker—She was telling you this the woman or her husband

The Witness—Her and her husband—and decided she had formed a habit and brought her to me to treat her for it

Mr Loesch *Q*—What did you do? *A*—I stopped the Wine of Cardui and gave her some sedatives and bromids

Dr Fennell stated that at one time he saw several men drink Wine of Cardui in back of a store.

CROSS-EXAMINATION BY MR. WALKER

On cross-examination the witness gave the names of several of the persons whom he saw drinking Wine of Cardui behind the store as well as other persons

The witness stated that his father and mother also saw the men drinking the Wine of Cardui He keeps some drugs, but does not conduct a drug store He has been a member of the American Medical Association for five or six years He first heard that a suit had been brought against the American Medical Association when it came out in THE JOURNAL of the AMERICAN MEDICAL ASSOCIATION He received a letter from the Secretary of the Alabama State Medical Society There was no letter from Dr Heizer enclosed Later the witness received a letter from Dr Heizer, whom he met in Birmingham He gave to Dr Heizer the names and addresses of patients concerning whom he testified

The witness came to Chicago during the last part of March, remained here a few weeks, returned home, and came back to Chicago again His expenses are to be refunded

The witness was then cross-examined in detail concerning the case of Mrs E. D and Mrs M B, which he described as on direct examination In treating Mrs M B he gave her syrup of iodid of iron and some quinin in capsules in powder form

The witness was cross-examined concerning the date on which he treated Mrs S He was asked in detail about the cancer growth in this case He was then asked concerning the date on which he treated Mrs J H and Mrs P B He answered as on the direct examination

Q—Now M S—she had hookworm? *A*—Yes, sir

Q—How long did you say she had been taking Wine of Cardui? *A*—She had been taking it off and on for four or five years

Q—For what? *A*—Four or five years taking Wine of Cardui off and on irregularly

Q—Well does the hookworm disease last that long *A*—It lasts a lifetime if you don t remove it, remove the cause

Q—Yes it lasts a lifetime but how long do you die after you get it? *A*—Some people die with old age, I guess, that have the hookworm

Q—You treated the hookworm, and did you say she got well? *A*—Yes sir

He was then asked in detail concerning Miss M S and Mrs C F

Q—Do you know what causes eclampsia? *A*—It is disputed, Judge There are several theories It is supposed to be toxins faulty elimination the kidneys and liver failing to do their duty failing to throw the poisons out and they remain in the system and cause it

Q—The toxic condition coming from the fetus in the womb—isn t that it—from the child? *A*—No but where it fails to throw the toxins out—uric acid and others—I think uric acid, they claim plays an important part in it

Q—Now, did you ever see any one besides these two women with eclampsia? *A*—Yes sir there are a lot of cases of it

Q—A lot of cases? *A*—Yes sir a good many cases

Q—Those are the two, however, that had taken Wine of Cardui— *A*—Yes sir

Q—What had the other one taken? *A*—There are three of those eclampsia cases that had taken Wine of Cardui

Q—What had they—you have seen a great many of them where they had spasms in pregnancy— *A*—They may have taken Wine of Cardui too and I don t know

Q—You don t know that they had taken it? *A*—No I don't know that they had—

Q—If you had a history of Wine of Cardui in any of those other eclampsia cases you would have given them here, wouldn't you? *A*—A lot of times I don t take down memorandums—nobody could remember all the Wine of Cardui cases we have in our country

Q—If you had a case of eclampsia where the person had been taking Wine of Cardui— *A*—If I remembered positively that they had—

Q—If they had told you about it, you would have testified about it here? *A*—Yes

The witness stated that he had had seven or eight cases of eclampsia of his own and had been called in consultation with other doctors when they have had cases The witness could not begin to guess how many patients he attended who had menorrhagia or how many with amenorrhea He has not had many pellagra cases He treated Mrs H S, who suffered with eclampsia with veratrum and morphin Instruments were used and the uterus was emptied In most of the cases of eclampsia the child died He has not had a case in which the mother died He was once called in consultation to a case but before he arrived both the mother and child died He cannot remember how many patients suffering with pelvic difficulties he has seen altogether It would be safe to say at least fifty a year and this will be true over the last fifteen years

Adjournment was taken until May 5, 1916, at 10 30 a m.

May 5, 1916, Morning

TESTIMONY OF DR WILLIAM O KROHN

The court met pursuant to adjournment Dr William O Krohn, Chicago, was called as a witness for the defendants

DIRECT EXAMINATION BY MR. T J SCOFIELD

Dr William O Krohn testified that he is a physician practicing in Chicago He received his doctor's degree in Yale 1889 He then taught for two years at the Western Reserve University Cleveland, Ohio He spent a year abroad in various German universities Returning to this country, he was made senior teaching Fellow at Clark University Worcester, Mass In 1892 he became head of the department in the State University of Illinois which position he held for five years From 1897 to 1900 he examined patients for admission to the State Asylum at Kankakee He did two years medical work at Northwestern University Medical School receiving his degree in 1905 For six years he was medical juror in the Insanity Court of Cook County He has been clinical instructor in dispensary work at the Northwestern University His time is largely given to nervous and mental diseases but he also does some general work.

Q—Doctor, what has been your experience, if any, with reference to the relation between abnormal conditions in the female pelvic organs and nervous affections in woman? A—My experience has been quite extensive in that connection We find a great many nervous conditions that are traceable directly to abnormal conditions in the pelvic organs of woman, depending in kind and degree somewhat upon the cause, somewhat upon the time that it is existent, somewhat upon whether it is an organic change in structure progressively receding, or growing worse. But we have all sorts of nervous diseases, nervous conditions, resulting from upsets and abnormalities or disturbances in the pelvic organs of woman

Q—How are these troubles or conditions treated, doctor, in a general way? A—In a general way you take each nervous disease as it is when it presents itself, as perhaps it may be more aggravated in its symptoms, and the symptoms will have to be alleviated for the time being But your fundamental, or your ultimate object is definitely to find the cause of a particular disease, and remove that cause That is, the particular disease, and remove that cause That is, the cause of the particular disease or of the particular nervous manifestations When you find the cause, no matter what pelvic condition it may be, you seek to eradicate that in so far as possible

Q—As a condition to the further treatment of the nervous condition? A—As an essential prerequisite to the cure of the nervous condition

Dr Krohn testified that he has had no experience with cnicus benedictus He used viburnum prunifolium for a year or two but found that it did not succeed so he discontinued its use nine or ten years ago

There was then read to Dr Krohn a hypothetic question similar to that asked of other witnesses He stated that he had an opinion as to the physiologic and therapeutic value *of the hypothetic medicine*

Q—What is that opinion? A—In my opinion you have described in your hypothetical question an alcoholic bitter, that is, an alcoholic solution, 20 per cent alcoholic solution, that contains a dash of bitters

PUBERTY

Q—Doctor, I wish you would explain what is meant by the term "puberty" in conjunction with the special experience which you have had, if you have had any? A—By 'puberty" we mean the developmental change that takes place in the unfolding of the boy and the girl from childhood to manhood and womanhood More particularly in this connection, I was a director of the work of examining, making physical tests and measurements also mental examinations and tests as to memory, power of attention and various mental faculties in 40 000 schoolchildren, showing the particular changes that take place at puberty, or pubescence

More particularly in the girl, we found that this developmental charge is characterized by certain periods or lunges of growth, physically first that this period of growth is an unfolding in a certain definite order, that all children grow in exactly the same order but grow at a different rate, so that we have a different length of time for the period of the female unfolding

We have at this period certain manifestations of this development In the first place there are certain changes in contour, in form and in size The child will shoot up like a weed for a little while, and then he will grow in breadth of chest and depth of chest and then in the contour of the body

The girl evidences it in the fulness of the breast, and in both boys and girls, there are certain other manifestations We find certain manifestations that are peculiar to the girl To illustrate, the establishment of menstruation, which comes on some months, even as long as a year and a half, after the period of puberty has begun to be initiated This may be established in the course of one month or two months—that is, the menstruation, I mean, may be established in the course of one month or two months or six months or a year or more, but the period of pubescence is a period of development including these physical and mental changes that take place before the establishment of menstruation and certain other changes that take place after the establishment of menstruation

We have, on the nervous system side, certain peculiarities that are due to this period in its unfoldment We have the instability we have the irritability, we have what the Germans call "the period of storm and stress," where these emotional outbursts, these emotional and erratic tendencies show and when certain characteristics assert themselves which are developing in them as they become sexed and which cause them to clash with school discipline, with authority at home and in school and they come in clash with the discipline and they drop school because of this irritability and these conditions that are the result of the reaction of their nervous system peculiar to the period of puberty

Q—Now then, Doctor, you have described, as I understand it, the period of time that may be required for the establishment or development of the menstrual flow But I do not understand that you have stated the length of time that may be required for the establishment or development of puberty itself A—Puberty in Illinois—that is the result of the measurements on 40,000 schoolchildren, the average time is three years. That varies a little in different latitudes I am speaking of the girl now With the boy it takes a little longer to be established and there are some other things, the change of voice and so on, that are included in the puberty period in a boy But speaking of girls, the average length of time is two and a half to three years in the United States

Q—Now, Doctor, have you an opinion as to whether every girl should take such a medicine as I have described to you in the hypothetical question, at the time of puberty? A—I have an opinion yes, sir

Q—Well, what is that opinion, Doctor? A—In my opinion, when we recall that this is the normal, natural, physiological evolution of the growth of the child from girlhood into womanhood, when we recall the peculiar state of unrest that the nerve cells are in, when we recall the particular groups of muscles that are undergoing growth changes at different periods, when you recall the changes in circulation, and in the various functions of the body, leading up to the establishment of menstruation and the settling into the individual's trend and bent afterward, to my mind the prescription or advice of giving such medical contents as you have described in the hypothetical question is absolutely and positively wrongful advice

It has no basis whatever—no justification and no basis at all for its being given, because of the vast possibility of harm that it will work out, harm, physical harm, I mean, merely physical harm and harm to the nervous system, I mean mentally and emotionally You have a high degree nervous condition and you give a medicine that is so largely alcoholic in content, you add fuel to the flame in these explosive nerve cells and you start certain nerve diseases that would otherwise be unknown in the life of that individual You instigate certain abnormalities, certain morbidities and certain deviations from the normal type that would otherwise—a type that would otherwise remain normal except for the giving of such a drug

Q—Now Doctor, are there any special troubles that sometimes occur in young girls at this period, at the period of puberty? A—There are distinct diseases that are characteristic, at least are common to this period, more common to this period than others, and some that are characteristic of this period

There are certain nervous diseases that attach themselves to this period in the life of every developing girl There are certain blood states that are peculiar to this period I might mention chlorosis, I might mention the disease involving nerve tremors, the diseases that are the result of malnutrition in the changes that take place at this period

The growing girl at this period requires her food not only for relieving the waste of destroyed tissue each day, but has to have material to supply the growth as well It is a period of most rapid growth in the life of a girl, and because of the instability there are certain nervous diseases that are peculiar to this time.

Q—Now, Doctor, what is the effect of alcohol as contained in the hypothetical medicinal solution, in these conditions, on the conditions which you have described? A—Alcohol given at this period of instability, at this period of unrest, at this period of storm and stress, cannot help but cause a greater instability and also interfere with the normal functioning of the body that would ensue were there not this alcoholic interference, so that you have certain diseases of an explosive type, certain forms of hysterical manifestations, certain forms of nervous weakness and tremors that are directly ascribable to an alcoholic medicine at this time

Q—Now, Doctor, have you an opinion as to whether a medicine, such as I have described, which contains 48 drops of pure alcohol to each dose should be taken by every girl, including the normal girl, at the time of puberty, and that such medicine can never do her anything but good? A—I have an opinion

Mr Hough—I object to that, if the Court please

The Witness—I beg your pardon

The Court—He may answer

To which ruling of the Court the plaintiffs, etc, excepted

Mr T J Scofield Q—What is that opinion? A—In my opinion, as I have already indicated, the statement that it cannot do any harm is absolutely unfounded in fact, is untruthful in other words and has no basis in medical fact, has no basis in—when we come to understand the physiological organization of the girl, and that to prescribe that or advise that as a general method of procedure is vicious It is more than vicious, it is absolutely wrong from a medical and psychological standpoint

MENOPAUSE

Q—Now then, Doctor, you have described the period at the beginning of the menstrual development in a woman Will you kindly tell us something about the end of the menstrual life in a female A—The period at the end of the reproductive cycle in woman known as the menopause or change of life, or climacteric, is a period that again is fraught with a host of regressive changes as distinguished from the changes at puberty

At puberty there is this hurrying up in growth, the impulse to grow and become larger and bigger It is the growing impulse In the woman, we have the loss of certain activities the loss of certain functions We have coupled with that the reflex effects of that loss or the reflex effects of the inactivities.

So that during this period that obtains from three to five years, that is, he climacteric, the change of life or menopause you have any possible nervous diseases from headache to forms of unconsciousness from mere minor pains to convulsive seizures, from merely temporary weakness to complete prostration, the exhaustion diseases, the diseases that are the result of the fatigue poisons, the diseases that are the results of malnutrition and the malnutrition is accentuated because of these modifications that are going on within the organism

You have all forms of vascular changes, blood circulation changes. We have the hot and cold flashes and we have the spinal symptom You have the lead cap headache at the top of the head pressing and pressing The disturbances that are associated with lack of the power of initiation, the inertness that some women have at this period, the lack of ability to initiate something new They simply drag along as a result of the nervous modifications of these repressive changes in the organism

We have of course these changes in the circulation in the pelvic organs causing changes of circulation in the adjacent viscera and as a result of that you have a looseness of the intestines the lax ligaments of the intestines and the liver dropping down and the abdominal organs and then you have that dropping down of the stomach and intestines and then you have the poisons locked up in the body, the fermentations from the decay of food and a host of diseases that are attributable to this period and are because of these changes

Q—From your experience what would you say is the average length or duration of the menopause? *A*—The average did you say?

Q—Yes *A*—From three to five years

Q—Have you an opinion Doctor, as to whether a medicine such as I have described should be taken regularly on the first sign of the change of life and its use continued throughout the whole period Have you an opinion? *A*—I have an opinion yes

Q—What is that opinion? *A*—In my opinion that is again very wrongful advice It is wrong as against the woman s own condition that is her physical condition It is wrong in its disguising of the true condition An alcoholic medicine or preparation, such as you have indicated in your hypothetical question, may make the person temporarily seem to be well when actually they are not well and are becoming less and less well and more and more sick

And then again the peculiar nervous depression and the peculiar physical depression that is characteristic of a large number of those cases make the ingestion or the taking in of any alcoholic medicine or alcoholic preparation a serious proposition for while the momentary effect of the alcoholic preparation would be exhilarating the reaction is more pronounced in a woman of this type in a woman at this period, and so while she may in the course of time, for a moment or a few moments or a few minutes, as the result of this alcoholic preparation feel better, she will partake of it regularly—but she will sink down in the trough of the sea further between the doses and she will seek to obviate this increased depression that is caused by this form of medication she will seek to obviate it by more frequent doses or by larger doses

Q—Doctor I want to read a quotation from the Ladies Birthday Almanac for the year 1907 copyrighted by the Chattanooga Medicine Company I read from page 9 under the heading Untold Misery '

> Woman Why let yourself be dragged down made miserable sere, yellow withered wrinkled and gray haired before your time by the pain you think you have to endure Untold misery is suffered every month by thousands of women for want of the right medicine to help their troubles Wine of Cardui Take it and it will help you as it has helped many others in the past 30 years No matter what the pain headache backache waist pain bearing down cramps colic and so forth caused by weakness or irregularity of your womanly functions, Wine of Cardui has been proved a successful treatment for their relief or cure"

Now then Doctor assuming that the hypothetical medicinal solution which I have described to you corresponds to Wine of Cardui have you an opinion as to whether the statement which I read to you is true? *A*—I have an opinion yes.

Q—What is that opinion? *A*—My opinion is that it is not true

Q—Why not? *A*—For the reason that you have listed there a host of groups of complaints of various headaches and symptomatic complaints that you have mentioned there that are due to countless varieties of causes.

If you would put in all of the drugs in the pharmacopeia you could not in any one solution cure all of those things. It would be impossible to reach and attack all those.

In the second place it is untrue in alleging benefit because it suggests to women at a period of life when they are most suggestible that there is something that will relieve anything that they may have It first suggests that they have these things, and the suggestion becomes more potent, more forcible as they read it over and over In fact the psychology of advertising is to list as many as possible and then as they read of these complaints, they find that they have not only one but they have two or three of these various things, and they are induced to take something at this period when these changes are most pronounced at the climacteric or menopause that will do them harm

Mr Hough—I suggest that that be stricken out, as not responsive to the question He was not asked to testify as an expert on advertising

The Court—No, but he was asked why it was his opinion that the statement was not true

Mr T J Scofield—That is the question

Mr Hough—The issue in the case is what the medicine will do

The Court—Yes, and this statement—

Mr Hough—Not what advertising might suggest.

The Court—This statement was taken from one of the advertisements of the plaintiff in this case

Mr Hough—The point I make is, that it is not an issue in the case

The Court—It stated certain things that this medicine would do as I recall the extract that was read

Mr Hough—And instead of saying that the medicine won t do it, he undertakes to say that that suggestion of a lot of things is one of the purposes of advertising, and that is not responsive

The Court—That was the opinion of the witness as to why he gave his answer It may stand, and you may save your point

To which ruling of the Court the plaintiffs etc, excepted

Mr T J Scofield *Q*—Now Doctor, I wish to read to you from the Ladies Birthday Almanac, for the year 1911 copyrighted by the Chattanooga Medicine Company I read from page 9

> Whatever you do, don t be nervous'

The quotation from the Almanac, is under the head of "Nervous Women"

> Whatever you are, don't be nervous. Nervous people don't live long they grow thin and tired and irritable lose sleep, catch cold and other troubles as soon as these ailments attack them and nearly always suffer from womanly weaknesses To relieve nervousness take Cardui the Woman s Tonic By helping build up the nerves Cardui helps the rest of the body and health is the result Are you nervous weak irritable sick? Take Cardui regularly and you are well It is harmless It does not cause a habit Take Cardui regularly until you are well It is harmless, it does not cause a habit. It acts gently and naturally, not like a powerful drug, but just like a mild herb remedy, which it is"

Doctor assuming that the hypothetical medicinal solution corresponds to Wine of Cardui what is your opinion of the advice given in this quotation to take Cardui to relieve such nervousness? *A*—In my opinion the advice is wrongful and without justification, for several distinct reasons

In the first place, the statements upon which it is predicated are, to a certain extent in error that nervous people don t live long and certain other things that are absolutely in error that nervous people are thin Some of the worst cases of nervous diseases are in fat men and fat women The premise is wrong to begin with

In the second place you have described here what to my mind is a distinct general—distinct type of nervous complaints which we group under the term or disease neurasthenia ' by which I mean a disease that is characterized by increased exhaustibility, and also by increased irritability Those are its nervous manifestations

You will find underlying those nervous manifestations certain pathological changes that are distinct and characteristic of neurasthenia You will find for example a process of fermentation going on in the bowel tract. You will find the distended baggy, boggy stomach with its fermentation, and with the retained toxins. You examine the urine of such a person, and you find the indican, the product of the fermentations that are going on

You find that the liver has dropped down, and the ligaments have become lax You will find that there is a general ptosis bearing down of all these organs

Now the hypothetical medicine that you have described, and which you have characterized as being of the type as was prescribed under these directions that you have read or the quotation cannot get at these underlying causes and cannot relieve the increased excitability, and cannot relieve the increased irritability that is characteristic of the disease

Q—Now Doctor what is your opinion of the following statement in the same quotation assuming that the nervousness is due to some female trouble Take Cardui regularly until you are well On the same assumption what is your opinion of the following statement It is harmless it does not cause a habit.' If you have an opinion state it *A*—Yes, I have an opinion My opinion is this That it will do harm and that it will tend in this nervous type that you have described or assumed that it will tend to the forming of habits.

The taking of any exhilarating remedy any remedy with alcohol content or any other exhilarating agent that makes a person seem more comfortable for a brief period, and then the reaction—they slip down and a nervous person will slip down further below the level that they were before they took the medicine—the pendulum swings back further and, as a result of that they feel a sort of need to get more exhilaration and they take more medicine and they keep on taking it because as they take it they are sure to get more reaction in between To obviate that reaction, they will take it more and more frequently and you have a habit formed as a result and the harmful effect

In other words the harmful effect of such a plan of procedure is such that the person makes their nervous system their enemy rather than their ally They have a nervous system that drags them down and hinders them and injures them in all of their activities rather than one that helps them and benefits them

Q—Now Doctor calling your attention to the Ladies Birthday Almanac for 1913 copyrighted by the Chattanooga Medicine Company and on page 27 of that book I read from an article under the heading Oh that headache

> Of course headache is only a symptom but it is a mighty miserable thing to have and when it becomes a regular visitor it begins to be a calamity Wine of Cardui will not act like a nerve deadener to kill the pain of the headache right off but it goes down to where the real trouble is and begins at once to remove the cause the female inflammation irregularity or other form of womanly disease In this way after a few doses, the headache most likely disappears and, when the real trouble is cured it stops those regular visits. Try the Cardui treatment for headache and other womanly pains

Now Doctor, assuming that the hypothetical medicine, which I described to you in my hypothetical question corresponds to Wine of Cardui approximately will you let us have your opinion as to whether such a medicine will cure the real trouble, as stated in this quotation *A*—I have an opinion

Q—Will you tell us what that opinion is? *A*—In my opinion the statement is not borne out by the facts at all, for the reason that, in the first place, you have as many as fifteen different causes of headaches Many of these causes, of course, you can find out from the location of the headache

That is, we know, if a headache is at the top of the head, that it is due to anemia or excitement or worry We have also a large number of headaches that are toxic, the cause of the headache is toxic, by which I mean either poisons that are developed within the body from fermentations, autointoxications, or poisons that are ingested with the food, from improperly prepared or improperly cooked food or food that is improperly contained in cans.

You get your generally described frontal headache You have certain headaches that are due entirely and wholly to eye disease, that is diseases of the eyeball You have other headaches that are due entirely to a shortening or lengthening, at least the incoordination of the external muscles of the eye You have certain headaches that are due to decayed teeth You have certain headaches that are due to ear disease You have certain headaches that are inherited with a nervous condition, the migraine headaches and other headaches of that type

Now the medicine that is advised, the hypothetical medicine and the medicine that is advised in this statement that you have quoted to me about going down to the origin or the seat of the trouble, does not reach and could not possibly reach the larger, perhaps the larger number of groups of headaches which I have listed

Then there are a host of reflex headaches, due to reflex irritation of the pelvic organs, that would be really accentuated by such a remedy There are certain headaches, where if you give any medicine that contains the least alcoholic content whatever, they will become more booming, more thumping, more painful, and more excruciating

Q—Now, Doctor, I read to you from the Ladies' Birthday Almanac of 1910, copyrighted by the Chattanooga Medicine Company, page 19, under the heading "Can't sleep"

> "When nature is too exhausted for sweet sleep to come and rest the weary mind and frame, take Cardui the Woman's Tonic Sleeplessness is usually a sign of tired nerves It is one of the symptoms of a nervous breakdown, and should have immediate attention By building up the nerves and womanly system, Cardui soon brings balmy sleep and restores the weary body to fullfledged energy and refreshment This method of treatment is safer and better in every way than the use of drugs opiates, bromids, and nerve sedatives It creates no habit but gently helps every part of the body to do the work as Nature planned it to do You cannot fail to get Cardui if you ask for it in any drug store"

Now then Doctor, on the same assumption, that the hypothetical medicinal solution corresponds to Wine of Cardui, I would like to get your opinion in reference to the statement in this quotation that it builds up the nerves and womanly system, and restores the weary body to fullfledged energy and refreshment *A*—I have an opinion, and in my opinion you have there stated in the first place a more profound form of this nervous disease, neurasthenia, of which I have already spoken

Now there is nothing in the hypothetical medicine that you have assumed, or the hypothetical solution that you have assumed, there is nothing there that will build up or increase the nervous strength of the individual It rather operates the other way

You have a case of profound fatigue in this nervous condition that you have described It is like whipping a tired horse to make it go a little further, because—to give a medicine that has the alcoholic content that you have assumed, you make it more tired

Instead of building up, there is nothing in it that will reconstruct You have not assumed any element in that that reconstructs the tissues, but you have simply given or used a sort of a whip to whip an overfagged, overtired nervous system

Now fatigue always engenders a poison in the organism You can not be fatigued without having poisons develop in the body The more profound that fatigue, the greater or more intoxicating is the poison The blood of a fatigued animal will poison another animal if injected into it

Now, this fatigue that you increase by your treatment by your whipping up will simply cause more destruction of tissue, more destruction of vitality, more weakness and all of those qualities that you have described in the condition of the woman in that quotation

EXPERIENCE WITH WINE OF CARDUI

Q—Now finally, Doctor, have you had any experience with Wine of Cardui? *A*—I have in two instances only

Q—Will you please relate your experience? *A*—The first is a case of acute alcoholism, and it came under my direction as an emergency matter while I was visiting or attending to some of my—well, it was a farm or plantation down South, at Summerdale, Alabama There was no physician located there The woman had become very much disturbed and was showing certain marked signs that alarmed a neighbor woman, and also alarmed her own family I was called in simply as an emergency matter, not as practicing in Alabama, but to afford what relief I could

I found a case of acute alcoholism She was drinking nearly an entire bottle of Wine of Cardui in one day and I had to treat her for the acute alcoholism

Another case was in this same town, a case where a young woman of 23 or 24, evidently without any peradventure of a mistake, suffered from pellagra, and had been taking Wine of Cardui for three or four months, on the idea that it would build her up, and the Wine of Cardui had at least some—the habit of taking it, and the continued taking of it, and her faith in it for the time being, had obviated the treatment that she should have had in all those three months, to build her up and to obviate the actual fundamental effects of the disease

Mr T J Scofield—I think that is all, Doctor

CROSS-EXAMINATION BY MR HOUGH

Dr Krohn was cross-examined in detail concerning the time when he first began to practice and the various positions which he had held since that time, which he described as in the direct testimony He testified that if he had a case which required gynecologic treatment, he would turn it over to a gynecologist In prescribing viburnum prunifolium he used the fluidextract This he did in certain functional disturbances of the pelvic organs associated with certain nervous conditions The results were unsatisfactory He used it about a year and a half in fifty-five or sixty cases, covering the years from puberty to the menopause but not the whole range of female troubles He feels that he gave it a sufficient trial to justify his conclusion that it was not therapeutically active The longest period of time in which he used it was about eight days in the same individual and twenty-four days within a period of three months, given three times a day and two teaspoonfuls at a dose When he gave the drug he expected to get the effect of the whole prescription and did not consider the question of the alcohol He does not know whether the alcohol had any deleterious effect

Q—If a doctor gives a medicine, or prescribes one, which has three or four different ingredients, he expects that each ingredient will have some definite action, don't he? *A*—No, not necessarily, because there are certain aromatics and certain menstruums and so on that are in the preparation They are not all—

Q—You mean you consider the alcohol in this purely as a menstruum? *A*—No, I did not. I thought it was preservative of the drug and extractive, perhaps That is my impression now I don't know really what I thought about it, ten years ago I know I did not think very much of the medicine, but what I thought about it, I do not know

The patient to whom the viburnum extract was given as described is now alive She did not get well of her pelvic trouble The nervous trouble was corrected in about four weeks The patient was a young woman, 20 years of age, a patient at Mercy Hospital, now residing in California Dr Krohn treated her in 1906 He did not in any case continue the viburnum more than a week He cannot remember that he used it through a menstruation period He did not figure how much alcohol the patient was getting

Dr Krohn was asked what medicines he used that were better than viburnum prunifolium when he abandoned it In menorrhagia he found fluidextract of ergot better In dysmenorrhea he secured better results with cannabis indica

Q—When you defined puberty, don't you think you confounded it with pubescence? *A*—Puberty and pubescence are the same thing, sir The period of puberty and the period of pubescence are the same though the term "pubescence" is used oftentimes in contradistinction to adolescence or senescence and is given a wider latitude, but really they mean the same thing

Q—Isn't puberty, properly speaking, simply the establishment of the menstruation? *A*—Not at all, sir, no more than the mere change of the voice of a boy is the establishment of puberty or the growth of hair on certain parts of the body is the establishment of puberty

Q—Wouldn't you say that the completion of the establishment of menstruation has been called puberty? *A*—I might say that it might have been so called, possibly erroneously so called, but puberty is, as I have defined it, the whole period of developmental change with all the incidents that occupy the time of this change from girlhood to womanhood and from boyhood to manhood when these nerves and organs are making their rapid growth and the groups of muscles the canalization of the heart is changing, the blood changes and all that is included in the term "period of puberty"

Q—You say, then, that the period of puberty could never be limited to one month or two months or even three months? *A*—The period of puberty can never be correctly limited to one month or two months or three months

Q—What do you mean by "correctly limited"? *A*—Because it would be a misuse of the term "period of puberty" It is impossible for all the changes that are included in the term 'puberty" to take place in three months, or to take place in one year

Q—Would you not say that puberty is the appearance of the menses, or menstruation, and that when that is established, that covers puberty? *A*—Not at all, sir As I have sought to answer explicitly before, that is not at all the meaning of puberty

Q—Is the definition of puberty a matter of individual opinion or is it based upon the definition given the term in medical works? *A*—

It is based upon—by 'period of puberty' you mean to include the changes that take place at this period Now then to take your question a moment before and we apply puberty to the boy as well, and puberty if it meant only the establishment of menstruation—we would have to have a male term and puberty would be the female term But puberty means all of those changes that take place at this time

Q—But when you use the term as applied to the female don t it relate to the establishment of the menstruation? *A*—There is no warrant in the world Mr Counsel for making it a more limited term in the life of the girl than in the life of the boy so far as the time element is concerned because it includes in addition to the changes peculiar to sex it includes also the same changes that take place in the boy

Mr T J Scofield—Doctor, won t you turn a little more this way, so that we can hear you

The Witness—I was getting interested in the question that is all

Mr Hough *Q*—Would you say that this definition is correct or incorrect The age at which —under the term puberty '—

The age at which the reproductive organs become functionally operative It occurs between 12 and 17 years of age and is indicated in the male by change of voice and seminal discharge and in the female by the occurrence of menstruation

Is that an incorrect definition? *A*—That is not technically a definition of puberty at all I do not think as you read it, really it defines puberty I wish you would read it again sir

Q— Puberty the age at which the reproductive organs become functionally operative ' *A*—There is the point, exactly, Mr Counsel

Q—Wait till I finish *A*—Oh

Q— It occurs between 12 and 17 years of age and is indicated in the male by change of voice and seminal discharge and in the female by the occurrence of menstruation *A*—Now if you analyze that definition yourself Mr Counsel you will see that it is the period at which such and such takes place and it is indicated—that is the expression of puberty in the boy is so and so and the expression of puberty in the girl is so and so and as you read that language as I understand the way you read it, it does not mean what you are trying to have me say it means

Q—Do you make a distinction between at the period of puberty, and during the period of puberty ? *A*—No A distinction can be made At the period of puberty and during—

Q—Not at the period of puberty — *A*—Well, at puberty means at the period of puberty

Q—Then you make no distinction between those two expressions? *A*—Not as a general proposition no

Q—May menstruation be established in one or two months time? *A*—Menstruation?

Q—In a girl? *A*—Menstruation itself yes may be established in a short time.

Q—Well when menstruation has been established isn t that the end of puberty? *A*—It is not It is simply a sign that puberty has gone so far that the menstruation is established but it is not complete it has not completed itself

Q—Is nubility a part of puberty? *A*—I do not know what you mean by nubility

Q—You do not know what nubility is? *A*—I heard of it yesterday for the first time.

Q—You never read it in any of the medical books? *A*—Oh I never recognized—I have never recognized the word as you have given it no sir

Q—Have you ever read Dr DeLee s book? *A*—Which book?

Q— 'The Principles and Practice of Obstetrics' ? *A*—No I read his original manuscript, however the notes of which that book is the outgrowth that is the typewritten copy some years ago

Q—Did you ever read Dr Webster s book J Clarence Webster? *A*—No I have not read much gynecology of recent years

Q—At any rate you do not know what nubility means? *A*—I have so stated

Q—Well now in common parlance isn t puberty used as referring to the establishment of the menstrual period? *A*—Common parlance—you mean among the mass of people that have to do with children?

Q—Yes *A*—No it is not so used Every schoolteacher knows better

The Court—Is it not generally understood by the laity that when a young girl begins to menstruate that she has reached the age of puberty?

A—Yes she has reached that age your Honor But I did not so understand the Counsel s question

Mr Hough—Now no matter what might be said in any advertisement a girl is not likely to take any medicine at that period unless she has some symptoms which she regards as painful or distressing is she? *A*—Well she is not likely unless—this is what would happen naturally a girl at that time has all sorts of erratic symptoms chiefly nervous however, and her mother or guardian or friends or some neighbor will say Why such and such is good for it, and they take it or send for some of it, and they get the directions that it is very good cannot do anything but good can do no harm, and that it is of great benefit.

Dr Krohn stated that if the patient went to a physician he would give her medicine if medicine was indicated, if there was malnutrition or anemia certain drugs would be prescribed In chlorosis drugs are given to increase the volume of blood and to increase the oxygen carrying capacity of the corpuscles In anemia due to the result of hemorrhages, blood transfusion may be indicated In other anemias, beefsteak, lettuce, spinach and green vegetables containing iron might be given

Q—You mean you don't give medicines now as a rule? *A*—I did not so state but I say I would try to give the medicine in a way that would cause the least change of program in that girl s life In other words I never like to impress a pubescent girl with the idea that she is sick, or is an invalid because at this stage she is so impressionable and so I like to make my remedial agencies fit into her daily life and program

Q—One moment. When you give a diet that way, you don t call that drugs do you? *A*—I said remedial agency

Q—I asked you did you ever give drugs for those conditions, drugs by the mouth? *A*—I have so stated, and I say, in addition —

Q—I am not asking you anything in addition *A*—I thought you said you wanted my entire treatment

Q—Do you give drugs by the mouth for any of those conditions? *A*—Yes

Q—What drugs? *A*—I have already stated that I gave bromid of gold and arsenic I have already stated that I gave iron I have already stated that I gave magnesium sulphate, and I think almost any of the salines increase the volume of blood

Q—Have you at any time ever given any of the fluidextracts to a girl at puberty? *A*—No, not for anemia

Q—Have you for any purpose? *A*—I thought you were still talking of anemia I do not recall any specific fluidextract that is specially given at that period

Q—I don t mean whether you recall any that is especially given I say have you ever given any at that period? *A*—Oh yes

Q—What have you given? *A*—As I stated before, I temporarily gave this fluidextract of viburnum for a year or so to certain pubescent girls I have given as I said before the extract of cannabis indica for certain other conditions I have given—if at the puberty period they would have certain congestion of the lungs and so on there are some of the fluidextracts in the loosening cough mixtures that I would give If a heart tonic were indicated—the mere fact that she was at puberty would not put her outside of the domain of receiving proper drugs for that condition

Q—You did not consider it dangerous when you gave her that drug did you? *A*—Gave her what drug?

Q—The drug which you say you gave The fluidextract of viburnum among other things and other drugs containing alcohol you did not consider that you were doing a dangerous thing for the girl? *A*—No not for the time and in the amounts I gave them as I said Six or eight drops of cannabis indica for four or five days, and the other medicines for a few days I did not consider that I was working any harm

Q—You know that cannabis indica is indicated as a habit forming drug do you not? *A*—Not in the time I gave it.

Q—Without reference to the time it is indicated as a habit forming drug isn t it? *A*—It is a drug that is used habitually by certain people.

Q—Well it is hasheesh, isn't it? *A*—Not exactly but here to explain myself—

Q—Why don t you answer whether it is indicated or is not indicated as a habit forming drug? *A*—I am trying to answer

Q—Well, answer yes' or no ? *A*—It is not indicated in the way I gave it and under my directions In the first place—

Q—You mean then that a habit forming drug a certain drug might be habit forming if given by one person but as given by you it would not be habit forming? *A*—If you will let me complete my answer—

Q—Just answer that question *A*—that last question will not be necessary

Q—Just answer that Do you mean to say that a drug would be habit forming if given by somebody else but if given by you is not habit forming *A*—I did not so state and I do not intend to so state. What I mean if I may explain—

Q—Go ahead *A*—is this in giving cannabis indica the fluid extract the maximum dose of eight drops for four or five days the patient not knowing what it is, not knowing what the solution is or what it contains and not having the solution that is accessible to them or that they can give any definite amount of and giving it under the restriction I was or that it would be given in the first place only enough of it prescribed only enough of it given for that case and for that particular instance and no one knowing what it is that is being given them or that is giving them the effect of freedom from pain, there is no way in the world in which they could increase the use of it because it is properly safeguarded in the way it is being administered

Q—That is just lately that it is being properly safeguarded isn t it? *A*—I do not think so I have always properly safeguarded it in my method of giving it.

Q—It is known as a habit forming drug is it not? *A*—And I repeat that it has been used as a habit forming drug

Q—Is it not a habit forming drug? *A*—It has the possibility of being a habit forming drug when it is given promiscuously without restriction and without any safeguard whatever as to amount To give it to your little pubescent girl and say 'Now here is some cannabis indica now take it, and give her a whole lot of it—then she can take it more, and more and more. But that is not the way you give it. Cannabis indica as I give it, is not a habit forming drug because of the method of my giving it.

Q—Referring to this habit forming drug you mean the cannabis indica and not the alcohol? *A*—Well the alcohol in eight drops of cannabis indica—

Q—That is mostly alcohol, isn't it? *A*—Well, if it were all alcohol, I would not consider eight drops of alcohol given at the most three or four times in any one course of illness, would be considered in any sense as a habit forming drug, as part of a habit forming picture, or of a deleterious picture

Q—You have given as much as eight drops at a dose of cannabis indica? *A*—I have, yes

Q—Don't you know that that is regarded as a dangerous dose? *A*—I know that it is not regarded as a dangerous dose

Q—Is it not so marked, as a dangerous dose, in the pharmacopeia? *A*—It is a dangerous drug, but you don't give eight drops at the first dose, as a rule, unless you know your patient, but the dose is anywhere from three to four or five to ten drops

Q—How many drops of alcohol at one time would you regard as a dangerous dose of alcohol? *A*—I don't regard—

Q—I mean, diluted with five times the amount of water? *A*—I don't regard, in terms of drops using the term "drops" as you seem to indicate, that any drop dose of alcohol was a dangerous proposition, unless you would run it up into the hundreds or scores or thousands of drops Then you would get to the danger point

Q—If you should take 48 drops of alcohol— *A*—In one dose?

Q—and add five times the amount of water, so that you would have a tablespoonful of liquid, would you regard that in one dose, as a dangerous medicine or drug? *A*—In one dose? Not necessarily

Q—Then you did not mean what you said on direct examination, that giving any medicine with alcohol in it was dangerous? *A*—I meant exactly what I said on direct examination, and everything that I said

Q—Do you now say that giving any medicine—giving any person any medicine which contains alcohol is dangerous? *A*—If you give it as medicine, as giving medicine as ordinarily employed, giving more than one dose If you restrict it to one dose, then I would accept your corollary

Q—Suppose a patient comes to you, and you give them medicine to be taken three times a day, which contains as much as 48 drops of alcohol with other things, would you consider that you were giving them a dangerous medicine, or that it was an improper thing? *A*—I would, if I gave them a pint or a quart of it, I certainly would

Q—I am talking about the first dose *A*—Just the dose, one dose, I would say 48 drops of alcohol—I would not think that giving it in that one dose would be a dangerous proposition

Q—Suppose you would give them that same medicine every four hours for four or five days Would you consider that dangerous? *A*—I would not give it

Q—You would not give it? *A*—No, sir

Q—What is the largest amount you would give them for as long a period as four or five days? *A*—It would depend entirely on the patient If it were an old drunkard that I was treating for some disease, I would have to put more alcohol in it

Q—We are talking about a girl at puberty, and I am confining myself to that *A*—I did not so understand you

Q—What is the largest amount of alcohol by percentage which you would consider safe to give a girl during that period, if you were going to keep up the treatment for as long as five days at a time? *A*—The largest amount I would give would be the least amount I could possibly give, and give the remedy that was indicated

Dr Krohn then stated that he is familiar with the drugs that fall in his own line, that he knows that there are drugs in the pharmacopeia that contain more than 48 drops of alcohol per dose, but they are not given without prescription He then testified concerning the quantity of alcohol received by the patient to whom he prescribed viburnum prunifolium for eight days in the various dosages given He gave the drug on the assumption that it would do good

Further hearing of the case was adjourned until 2 o'clock of the same day

May 5, 1916, Afternoon

TESTIMONY OF DR WILLIAM O KROHN (*continued*)

Dr William O Krohn resumed the stand for the defendants

CROSS-EXAMINATION BY MR HOUGH (*continued*)

Dr Krohn stated that he might give a different medicine for malnutrition at puberty than what he would use in cases of chlorosis or anemia He defined the difference between malnutrition and anemia He stated that the words "at the time of puberty" and "during the period of puberty" would mean the same thing unless qualified He would say that puberty is not pathologic, and that the processes which occur at puberty are not pathologic although certain individuals may have pathologic processes Pain may occur but is not necessarily pathologic He could not conceive of any condition in which viburnum prunifolium or drugs of this class would be indicated for anemia at puberty Medicines may be used during puberty for pathologic conditions

Q—For what conditions would medicines—or is medicine ever given by yourself, or the doctors, that you would not consider are pathological? *A*—Well, I would say, for example there are certain times when a laxative is indicated, the condition is not pathological, in the sense that there is any disease or a disease element, but you wish to avoid pathological conditions arising and you discount them by treating them in advance There might be some congestions—some that we would require to prevent pathological conditions arising There are certain congestions There might be certain nervous indications of an oncoming pathological condition that you can obviate by a little treatment. You can prevent the full explosion of a possible disease focus

Q—There is such a thing then as preventive medicine, is there? *A*—There is distinctly so, yes, sir

Q—And is that ever practiced in case of girls at puberty? *A*—Yes

Q—That is, to prevent something that might happen? *A*—It is to prevent something that you think is likely to happen, if you don't interfere

Q—What class of medicines would be used for that purpose as preventive medicines? *A*—It depends entirely on what the conditions are in each individual case There is no general medicine that you can prescribe for any period or for any sex or for any age, but you have to take up each individual, each distinct diseased condition as it presents itself

Q—When you were using viburnum, did you use it for any such condition as that, as preventive medicine? *A*—No, I do not think so I used it largely on its reputation, I used it as an entirety, a medicine that was expected to do certain things

Q—Have you ever used preventive medicines for girls at puberty? *A*—I have so stated—yes

Q—What medicines have you used? *A*—Well, it depends entirely again on what condition is presented at first. There are certain conditions that are due to stagnation of the intestinal tract There are certain conditions that are due to improper habits of sitting and dressing, which require a certain stimulation, the result of methods of living have to be corrected, in order to make their puberty life normal, animal development

Q—Now, what medicines have you used for any of those conditions? *A*—Well, as I have stated, if a laxative was indicated I would give the best one that is appropriate at that period, saline laxatives, with perhaps iron, if there is any indication of chlorosis—if the blood examination showed any anemia—

Q—Outside of laxatives what medicines have you given? *A*—If it was a congestion due, say, from functional retardation—

Q—Now, one minute You are talking about preventive medicine? *A*—Yes, and to obviate—

Q—That is where no pathological conditions exist? *A*—I understand

Q—Yes, all right *A*—But there are nerve signs, or other signs that a pathological condition may be imminent, and in order to prevent its realization, then you meet the condition

Q—Now, there are symptoms, I take it, which suggest the use of preventive medicines, are there? *A*—Symptoms, or signs, physical signs

Q—What would you call the symptoms or signs? What would they usually be? *A*—They would be—they might be one of many things, or might be a group of many things If, for example, you find as one sign, the school headache, a typical disease entity, as another sign you would find lack of—well, a sort of stasis because of lack of proper exercise, the enforcement of certain conditions—or, as you take it in these girls that work in the stores in unhygienic surroundings, you have to assist by supplying the thing that is called for We have signs that this girl is becoming pale, that she is becoming tired easily, that she has a certain type of headache, that she has a certain muddiness of the skin, that she has a certain paleness of the lips, that she has that greasy white tongue, all of these things are signs or indications that something should be done to prevent the girl from becoming a less efficient wage earner

Q—And viburnum has been, in the past at least, a very common remedy for that condition hasn't it? *A*—I don't know of any case where it is a remedy for that condition

Q—Don't you know that it has been very generally used in that condition? *A*—I do not know it

Q—Have you ever been connected with any girls' schools? *A*—Yes

Q—Don't you know that it is always kept and given there? *A*—I do not know that it is

Q—Don't you know that Hayden's viburnum compound is? *A*—I do not know that it is. I do not know—I know that where I was associated, at any rate, it was not in evidence

Q—What schools were you associated with where there were girls at puberty—the age of puberty? *A*—Well, I had charge of the examination of physical condition of the students that were indulging in gymnastics, et cetera, at the Hyde Park High School in this city, and one or two of the district schools in my vicinage, and also at Cleveland I had some work in that connection

Q—Was there a medical department in connection with these schools? *A*—You mean a medical man—

Q—Or a medical woman who dispensed drugs to girls who needed it for the purposes we have been talking about? *A*—Not so much drugging as proper advice and reference

Q—Is there not a medical department in connection with large stores in which they dispense medicine? *A*—There is, yes

Q—And don't they always give the viburnum in some form? *A*—I don't know that they do I do not know

Dr Krohn has not been connected with any school in which there are dormitories for girls He was connected with the medical department of Northwestern University and not with the College of Liberal Arts The latter has a medical department but he does not know that they dispense drugs

The menopause is frequently attended with pathologic conditions but it is a normal condition

Dr Krohn has used pulsatilla but he did not prescribe it for women He has also used cimicifuga He testified that alcohol is always a physical exhilarant in the initial stages The reaction is one of depression A large enough dose of a sedative drug in an alcoholic solution would counteract the effects of the alcohol He used remedies as combined and noted their final effect, without reference to the percentage of alcohol

Dr Krohn was then cross examined in detail concerning the case which he saw at Summerdale, Ala He does not know whether the husband of the woman is still living at that place *He still owns property in that vicinity* He was last there in March, 1914

He testified in detail concerning the incident in which he saw this woman She was in a state of confusion and delirium when he first saw her and began to show signs of coherency and clear perception about six hours afterwards The history of the case was given to him in part at each of his four visits The husband of the woman told Dr Krohn that she was a "Cardi Fiend" Dr Krohn saw a Cardui bottle in the room, there was about an inch of fluid remaining in the bottle The room was 12 feet wide There was no carton on the bottle Dr Krohn believed that he could not have been mistaken The patient stated that she had not taken any Cardui for some weeks before but she felt she had to have it, procuring it, she took more than she should have taken The patient stated that she had not been drinking anything else for about a month prior to this time She had taken the contents of the Cardui bottle with the exception of the fluid that remained, in ten hours time He knew what was meant when the husband of the patient called it "Cardi" as he had heard it called that by other natives in the same district

The patient was not well when Dr Krohn left as she had nausea and vomiting but she was beginning to take nourishment without regurgitating it

Q—Now would you say that that amount of this hypothetical medicine containing 20 per cent. of alcohol taken through a period of ten hours, would produce delirium in a person who was normal? *A*—Well it could and would in some individuals It would not in every individual It would not in the vast majority but there are those who have such little toleration of alcohol, taken on an empty stomach that it would

Q—Well let us take a woman who had not had any alcohol for a month would you say that amount would produce delirium? *A*—Yes it would in an impoverished person a hungry person a person without food in the stomach—it would do it—could do it in a great many cases

Q—Did you ascertain that she took no food during those ten hours? *A*—I know this they had no money for food I know as a matter of charity some of us people bought food and I know the women of the town were supplying food to this woman who spent her money for Cardui.

Q—How much money had she spent for Cardui? *A*—I know she spent for that one bottle, that is all I know

Q—How much was that, one dollar? *A*—That was the information they gave me.

Q—That is one dollar for Cardui in one month—is that the only money they had? *A*—Only that one day

Q—But they had not had any for a month before that? *A*—They had not had any dollar before that

Q—That is what I say they had not had but a dollar for a month—you ascertained that did you? *A*—I ascertained from the history that that was the first she had had for a month

Q—The man was working in the turpentine camp all the time? *A*—No it was not the turpentine camp as I stated—the man was working for this laboring crew that were gathering these fat stumps and shipping them to this turpentine factory

Q—At any rate, he was working steady? *A*—Steadily as work was offered

Q—Was he a white or black man? *A*—White

Q—How many children did they have? *A*—Four

Q—And what was his *name*? *A*—Well I have been trying for the last two minutes to think of the name. I think I can secure it for you

Q—Well Doctor you have known for quite a while you were going to testify to this? *A*—No I did not

Q—You didn t? *A*—No

Q—Did you try to think of it before today? *A*—Well no I had not thought especially with reference to the name it is simply the incident that impressed me But, as I said, Mr Counsel, I think I can secure the name for you and be very glad to supply it to you

Q—When did you first think of referring to this incident? *A*—Why, I had not thought of referring to it—I simply—it made an impression upon me at the time, and I think perhaps this morning a little discussion as to the testimony of some of these southern physicians as to what Cardui had done in certain instances—I simply *spoke of one or two instances in which I had seen it*

Q—Did anyone go there with you? *A*—There were ladies of the neighborhood or the village that took food there

Q—You mean at the hotel? That took food at his place? *A*—Took food to—from the hotel to this cottage home A little girl came over and asked for food first—that is the first that we knew they were in poor circumstances—they asked for food three or four days before this incident

Q—Do you know the name of the little girl? *A*—Her first name?

Q—Yes? *A*—No sir, I don t believe I do

Q—Is there a doctor in that place? *A*—There was no doctor there and I believe there is none there now

Q—You did not go there prepared to practice? *A*—I have already stated I was simply there on a business trip

Q—Where did you get the stomach pump to pump out the stomach? *A*—Well that was not a real stomach pump It was one that I improvised

Q—Well what did you improvise? *A*—I improvised a rectal tube in the end of a funnel

Q—But you said you used a stomach pump, didn't you? *A*—Well it was a stomach pump for that day and that night

Q—Now just how did that work? It was not a pump at all was it? *A*—It was a stomach pump, yes sir

Q—How did you work it? *A*—Filled the siphon full of water with soda in it and held it up after I pushed this tube down and held it up after it was filled full turned it over and the contents of the stomach ran out

Q—That is you— *A*—Siphoned it out

Q—You mean you sucked it out? *A*—Siphoned it out.

Q—How did you start it? *A*—As you start any siphon You have a tube full of water and then let go of it and it runs right out

Q—Well you have got to have the receptacle from which the liquid is drawn higher than the highest point of the tube don't you to siphon it out? *A*—Well that is easy if the person is in bed you can put the end of the tube on the floor where the basin is

Q—And lift her up? *A*—No you do not have to lift her up just lift the tube down on the—

Q—But it has to come out of her mouth, doesn t it so that the mouth must be lower than the stomach? *A*—No You can bring it right up from below it will come up through the mouth—

Q—Quite right, but when you do that, you have got to start to suck it haven t you— *A*—No

Q—to get it up there? *A*—You are mistaken

Q—Do you do anything of that kind? *A*—I said I did not, and it was not necessary You don t have to

Q—That is it will run uphill first, by itself, and then run down? *A*—It will run out on the floor and run out in the pan

Q—Now what else did the man tell you about how frequently his wife had gotten drunk on Cardui? *A*—There was nothing else as to any frequency

Q—Just one time? *A*—Yes, sir He was simply alarmed about her condition at that time

Q—Now what was the name of the company for which he was working? *A*—I say I think that he was working for *individuals* who took contracts like—probably one man who had a team would take a contract to haul out so much to haul at *so much a cord* haul this fat wood from the pine woods and pine stumps That is the way it is usually done there There is Pete Johnson—and four or five fellows that had teams that would hire these men to gather these stumps

Q—Did this man work for Pete Johnson? *A*—I do not recall

Q—What was the name of the—any of the ladies who took food to this family? *A*—A Mrs Barnes.

Q—What Barnes is that? *A*—Mrs A B Barnes.

Q—Do you know whether she lives there now or not? *A*—*The last* I heard of them they did She was there.

Q—Did she have a husband? *A*—She was in New York last summer with her little child—at Montclair N J but her *husband* was still living there. He was the superintendent of the tobacco plant and I think she has returned there after the summer s heat was over

Q—You mean the tobacco plant near there? *A*—Sir?

Q—You mean the tobacco plant where? *A*—The tobacco plant is at Summerdale, that is the warehouse of the *tobacco* company

Q—What were the names of the other ladies? *A*—Mrs. Francher and Mrs. Barnes are two that I remember as taking food there

Q—Did the both of them—or rather Mrs. Francher, does she still live there? *A*—I *think so* sir

Q—Was she a resident there then? *A*—Yes sir

Q—What was—what did her husband do? *A*—He was a land agent.

Q—You say you think you can get the name of this person? *A*—Yes I shall endeavor to do so sir

Q—In what way do you think you can get it? *A*—Well *I will* write—I thought first of writing to Mr Barnes because of his wife being concerned in taking food there—I thought I would write and find the name through *them*

Q—Did Mr Barnes go with *you* or *know* that you went over there? *A*—No—oh he probably knew that I was going there yes.

Q—Do you recall the name of the hotel keeper where you stayed? *A*—Yes Mr Morgan tive Wassermann, apparently present cases of true reinfection In the absence of an absolute means of determining when a cure is final and complete, however, there is even in some of these cases a possibility that it concerns a recrudescence of a previous infection rather than a reinfection, the weak point in many of the reports being the very short time between the first and second infections Nevertheless the repeated occurrence of such cases tends to indicate that the present methods of treatment, if accurately carried out, are capable of eradicating syphilitic infection, and from this point of view true syphilitic reinfection may be regarded as encouraging evidence of the efficacy of the treatment

COTTAGE SCHOOLS

The *Weekly Bulletin* of the New York City Department of Health calls attention to an article by Todd[1] urging the replacement of the present style of "tenement" schools by buildings erected on the cottage plan In favor of this plan is the reduction of risk from infectious disease, particularly so far as such risk is due to the mingling of children from different rooms in the halls of the large buildings Todd considers the ground necessary for the cottage school plan one of its chief assets Much is to be said in favor of the idea that school buildings are a poor financial investment and that a simpler and cheaper as well as more hygienic style of construction would be preferable The one story cottage school almost entirely eliminates danger from fire, especially when proper material is used in its construction The elimination of stairs and basement increases sanitary merits and decreases the cost of construction The elimination of elaborate and expensive ventilating systems also cuts down operating cost

FRAUDULENT ADVERTISING IN THE DISTRICT OF COLUMBIA

Congress prohibits fraudulent advertising in the District of Columbia Why not within the entire federal jurisdiction? Congress has passed a bill, which was signed, May 29, by the president, prohibiting "fraudulent" advertising in the District of Columbia By this act it is made unlawful to display or exhibit to the public in any manner whatever, whether by handbill, placard, poster, picture, film or otherwise, or to insert or to cause to be inserted in any newspaper, magazine or other publication printed in the District of Columbia, or to issue, exhibit or in any way distribute or disseminate to the public, or to deliver, exhibit, mail or send to any person, firm, association or corporation any false, untrue or misleading statement, representation or advertisement, with intent to sell, barter or exchange any goods, wares or anything of value The act further prohibits the use of any of the methods of advertising described above with the intent or purpose to deceive, mislead or induce any person, firm or corporation into employing the services of the advertiser The House of Representatives committee report on the bill expressly states that it is designed, among other things, to prevent quack doctors and fake dentists from advertising their fraudulent nostrums, impossible methods and alleged results If the president and Congress agree that a law to prevent fraudulent advertising is a good thing for the District of Columbia, will they not agree that a similar law would be equally good for interstate and foreign commerce and for the purification of the United States mails?

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest, such as relate to society activities, new hospitals, education, public health, etc.)

ILLINOIS

Personal—Dr Frank A Stubblefield has been transferred from the staff of the Alton State Hospital to that of the State Hospital for the Criminal Insane, Chester He has been succeeded at Alton by Dr Van Pelt

Typhoid Dangers—The state board of health reports that Pana, Christian County, and Tuscola, Douglas County, are menaced by an epidemic of typhoid At Pana there are thirty-eight clearly defined cases of the disease and at Tuscola fifteen cases have been reported Sanitary inspectors are at work endeavoring to ascertain the cause of the epidemic

Chicago

Memorial for Dr Favill—A committee has been organized to establish a memorial to Henry Baird Favill under the auspices of the City Club and Commercial Club Drs Frank Billings and Emilius C Dudley are the medical members of this committee, which hopes to receive subscriptions amounting to $250,000

Surgical Society Election—At the annual meeting of the Chicago Surgical Society, June 2, the following officers were elected president, Dr William M Harsa, vice president, Dr William Fuller, secretary, Dr Kellogg Speed, and treasurer, Dr Frederick G Dyas

Mercy Hospital Wing Completed—The completion of the new $300,000 addition to Mercy Hospital was announced, June 4, and the formal opening of the building will take place June 15 The new building is four stories in height, and is designed especially for the care of sick children The outstanding indebtedness of the institution now amounts to more than $200,000, and the opening of the building will mark the beginning of a campaign to raise funds to wipe out this deficit

MARYLAND

Transfer of Quarantine—An ordinance authorizing the transfer of quarantine from the city of Baltimore to the federal government was introduced in the second branch of the Baltimore city council, May 22, and was referred to the committee on health

Survey at Frederick—A medical survey of Frederick is being made by officials of the United States Public Health Service, working in cooperation with the Franklin County officials, the secretary of the state board of health and Dr William W Ford, professor of bacteriology in Johns Hopkins University

University of Maryland Alumni and Graduation Banquet—The first alumni and graduation banquet of the medical and the general alumni association of the University of Maryland was held, May 31, at the Emerson, and was attended by over 500 alumni and graduates The following officers of the general alumni were elected president, E John W Revell, vice president, Dr Albert H Carroll, treasurer, William Stichel, recording secretary, Dr F V Rhodes, corresponding secretary, Edward P Crummer, and advisory council, medical Drs Charles E Sadtler, Arthur M Shipley and James M H Rowland

Personal—Dr Eugene W Heyde, Parkton, has been appointed one of the health officers of Baltimore County to fill the vacancy caused by the death of Dr Joseph S Baldwin, Freeland——The police commissioners have elected the following physicians as surgeons to the board Dr Caleb N Athey, president, and Drs James M Craighill, William S Gilroy, Thomas P McCormick and Elliott H Hutchins——Dr Philip Briscoe, Mutual has been reappointed a member of the Board of State Aid and Charities by the governor——Dr Bowers H Growt gave a reception to the members of the faculty and fifty-four members of the graduating class of the University of Maryland Medical School recently at his home

MICHIGAN

Sterilization Law Ruled Unlawful—Probate Judge Daniel Zuhlke Lapeer has declared unconstitutional the act of the legislature of 1913 which permits sterilization of inmates of state institutions The state started the action in order to test the constitutionality of the law and the decision will be appealed

Personal—Dr C Hollister Judd Detroit, has been elected chief of the medical staff of the Florence Crittenton Home Detroit——Dr Frank B Walker Detroit addressed the Kalamazoo Academy of Medicine, May 9 on 'Fractures of the Base of the Skull At the same meeting Dr Archibald D McAlpine Detroit read a paper on Lung Abscess"——Dr James C Martin has been reelected health officer of Highland Park Detroit

MINNESOTA

Health Survey of St Paul.—Surg George B Young U S P H S has taken active charge of the sanitary survey of St Paul The survey will occupy about three weeks and is undertaken in cooperation with the heads of the state and municipal health departments

Lutheran Hospital, New York, $3,000, by the will of Mrs Anna Hess

Montefiore Home, and Home for Aged and Infirm Hebrews, New York, each $1,000, by the will of Mrs Rachael H Pfeiffer

Jewish Hospital Association of Philadelphia, $20,000 for the endowment of a perpetual free bed in memory of Martin and Theresa Siedenbach, Federation of Jewish Charities, Philadelphia, $20,000, and Jewish Foster Home and Orphan Asylum, $20,000, by the will of Henry Siedenbach

WAR NOTES

Work of Surgical Dressings Committee—The Surgical Dressings Committee of Boston appeals for further funds for the carrying on of its work and reports that since October the number of volunteer workers under this committee have increased from 400 to 740, that eighty-seven branches have been established and that the shipments of surgical dressings abroad since November have amounted to 1,169,067 dressings, all of which were sent to the war hospitals of the allies The appeal for funds is endorsed by the Surgeons' Advisory Committee and by the Financial Advisors

Red Cross Supplies Appreciated—Letters of appreciation of the shipments of medical and surgical supplies to the Austrian Red Cross have been made on behalf of that organization to the American Red Cross by Gen Oskar von Zednik in which he states that the consignment shipped February 4 has reached Austria in perfect condition——The director of the Belgian Red Cross work in Calais, France, gratefully acknowledges the receipt of eight cases of war relief supplies shipped by the American Red Cross——The receipt of six cases of clothing for destitute children in Flanders is acknowledged in a grateful note—The Duchess of Sutherland, writing from Red Cross Hospital No 9, British Expeditionary Force, sends her grateful thanks for three cases of supplies recently received——Dr Joseph A Blake, surgeon in chief of the French Military Hospital, has received two cases from the American Relief Clearing House——Sir William E Garston, chief of the stores department of the British Red Cross, sends grateful thanks to the joint war committee for twenty cases of war relief supplies sent by the American Red Cross——Dr Ravenig writes from Rouen acknowledging the receipt of an American Red Cross shipment——The Marchioness of Aberdeen acknowledges the receipt of nine cases of war relief supplies received through the British Red Cross stores department, London, from the United States——Herr von Schelling, on behalf of the Central Committee of the German Red Cross, acknowledges receipt of seventy packages addressed to Dr Frederick Cameron and forwarded from the American Embassy, Berlin These packages have been forwarded to Frankfort, Hamburg, Wiesbaden, Bremen, Cologne, Hannover, Hirsau and Munich, as desired

PARIS LETTER

Paris, May 11, 1916.

The War

TRENCH FOOT

Drs V Raymond, of the military hospital of Val-de-Grace, and J Parisot, of the Faculte de medecine de Nancy, have just communicated to the Academie des sciences an interesting study of trench foot They consider the condition a peripheral neuritis Among the various etiologic causes which have been invoked, Raymond and Parisot attach importance only to cold damp They were led to the idea of a localized infection of the foot and set themselves to seek for the agent They have isolated a mold from the lesions, and by inoculation of pure cultures of this fungus in animals have been able to reproduce typical lesions similar to those observed in man, that is to say, edema, blisters and eschars They conclude that the condition called trench foot or frost bite of the foot is a mycetoma comparable to Madura foot It is not really a frost bite but a mildew of the foot. The fungus is found ordinarily in the infected soil, in straw, manure, etc, and it is brought into contact with the feet by the mud of the trenches It penetrates the tissues by excoriations or by the matrix of the nails Almost all the men who have remained in the trenches any time are afflicted with onychomycosis The local fall of temperature, resulting from standing in the water, favors the implantation of the fungus, for this parasite has its optimum development between 25 and 30 C (77 and 86 F)

These observations permit of indications for prophylaxis and therapeusis, namely, cleaning and disinfecting the feet by means of soap and camphorated alkaline, or better, borated solutions The results have been excellent Edema disappears in three days, and the neuritic pains in from fifteen to twenty days The eschars, characteristic of the graver forms are cured more slowly, but the treatment prevents the extension of the lesions, so much so that though the number of cases has been large, amputation of the foot has never yet been necessitated

MEDICAL QUALIFICATIONS AND PROMOTION

In a previous letter I have dealt with the decree providing for the special promotion of physicians and pharmacists in possession of certain academic or institutional qualifications (The Journal, Feb 12, 1916, p 522) M Prat, a deputy, has just drawn the attention of the minister of war to the fact that even though they may not belong to an academic body, physicians and pharmacists, owing to their academic qualifications and their scientific work, present special guarantees of knowledge and experience The deputy suggested that these qualifications and work should be accorded a fixed value and not one varying with the personal ideas of district officials, so that those officers whose reputation was beyond dispute should be assured a rapid promotion to higher rank and a military situation equivalent to their scientific position, in the same way as has been done for members of the teaching body M Prat received the following answer "In making promotions, special qualifications and scientific work of physicians and pharmacists are taken into account, but it does not seem possible to accord to these diplomas and work a fixed value giving the right to promotion"

THE ORGANIZATION OF THE CIVIL MEDICAL SERVICE

The minister of the interior and the undersecretary of state for the health service have been occupied with the organization of the medical care of the civil population, the supply of physicians having become insufficient in certain regions owing to the call to the colors of a number of physicians belonging to the auxiliary service or to the reserve It has been decided that the prefects and regional directors of the health service will deliberate on the distribution in the departments of the physicians who will be allotted to them In sectors having an insufficient number of physicians, the work will be carried on by surgeons of the army or of the reserve For recompense these will receive only their military pay and no fees The municipalities will provide them with traveling expenses or will furnish the means of transport

GRAFT TO SUPPLY LOSS OF A PORTION OF SKULL

At a recent session of the Societe des chirurgiens de Paris, Dr Maret showed several patients on whom he operated in May, 1915, after the following plan The graft consists of a portion of the external table of the skull, cut so as to be of exactly the same form as the area to be covered and a little larger This portion of the external table, covered with its periosteum, is completely detached on three sides, but on the fourth side, that neighboring the lesion the periosteum and fibrous adhesions are left and it is bent back on these as on a hinge The result is remarkable It is easier than would be thought to raise the external table of the skull bones (except, perhaps, those of certain regions, such as the wing of the temporal), especially in relatively young patients, those not over 40 years old

Personal

The Academie des Sciences has elected, as corresponding member in the section of medicine, Dr Yersin of Nha-Trang (Annam), former worker at the Pasteur Institute, well known for his work in bacteriology and especially on antiplague serum

Medical Epigraphy

Dr Raphaël Blanchard, professor at the Faculte de medecine de Paris, who interests himself greatly in the history of medicine has undertaken the publication of a *corpus* of all the inscriptions concerning physicians and biologists or those connected with medico biologic sciences The first volume of this interesting work has just appeared and contains no less than 1,258 inscriptions

LONDON LETTER

London, May 22, 1916

The War

THE EFFECTS OF THE WAR ON POPULATION

At the Royal Statistical Society two interesting papers on this subject were read Sir J Athelstane Baines showed that the relative number of the marriageable of both sexes in the population has risen considerably since 1871, but that the number who marry is proportionally smaller There is also a tendency to marry later, thereby shortening the productive period, and for the married to have smaller families A great decline in the birth rate had been the result especially since the beginning of the century Owing, however, to a similar decline in the death rate the rate of natural increase of the population, though generally on the down grade had been falling more rapidly of late as the births had been declining in number more than the deaths The distribution of the population by age and sex had been materially affected In regard to age the diminution of the number of children, which set in in the late seventies of the nineteenth century at first raised the proportion of adults in the prime of life and at the most productive ages It also tended to lower the death rate, which is at its lowest during adolescence and early middle life But as the diminution continued the people of middle life began to pass into the ranks of veterans among whom the mortality is almost as high as at the beginning of life, the death rate therefore tended to rise and the population to be older not by reason of greater longevity, but from the lack of reinforcements from below As the numbers at the productive ages grew smaller, the birth rate tended to decline, irrespective of less or later marriage or the voluntary restriction of childbearing As the mortality of females is considerably lower than that of males and as it is the men chiefly who emigrate the balance of sex is slowly inclining more and more on the side of women The short supply of children is not entirely irremediable, since it may be somewhat counteracted by the measures now being put into force for the preservation of infant life

Mr J W Nixon discussed the effect of war on national vital statistics He analyzed the statistics of births deaths and marriages in France and Prussia for the period of 1868-1873 and showed that both countries experienced a rise in the death rate in 1870 and 1871—the increase in the number of "civil' deaths being greater than the number of 'military" deaths This was especially marked in the case of France the number of "civil" deaths being 437,000 more in 1870-1871 than in 1868-1869 when the number of "military" deaths was at the most 150 000 The rise in the death rate was felt at all ages and shared equally by the two sexes Not only the two belligerents but the three surrounding neutral states of Belgium, Holland and Switzerland all showed a period of maximum mortality in 1871 England and Wales remained unaffected After the war, rapid recoveries set in in all countries except Prussia, the death rate in France falling in 1872 to 22 per thousand the lowest on record. A serious fall in fertility was experienced by France and Prussia in 1871, and the three neighboring neutrals similarly suffered a reduction in their birth rates There was a sudden decrease in marriage rates in France and Prussia in 1870 it was partly made up in 1871 on the conclusion of peace, but the year 1872 was a 'boom year in both countries, the marriage rate reaching the highest on record In the present war, England, France and Germany are experiencing a serious fall in the birth rate The death rate has not been seriously affected in England, the slight rise in 1915 being due to some extent to the bad winter and to an epidemic of measles On the marriage rate the effect has been the reverse of that in the Franco-Prussian war, a large rise having taken place last year The theory advanced early in the war that it was having the effect of increasing the proportion of male births—an old superstition—was found to be groundless The serious effect which the war has on the vital statistics of the nation is shown by the fact that the "natural increase' of population in 1913 was 377,000 In 1915 it fell to 252,000, exclusive of deaths of soldiers abroad

THE TESTING OF RECRUITS' HEARTS

As shown in previous letters, the military authorities are employing to the full all kinds of specialists both at the front and in this country The danger of accepting as recruits men whose hearts are not sound enough to stand the rigors of soldiering has been obviated in London by a new scheme In addition to the routine examination which every recruit undergoes at the enlistment depots, it has been arranged that every recruit whose heart shows the least abnormality shall be examined by specialists at the National Hospital for Diseases of the Heart "Please run up those stairs to the roof and back" the recruit is told On his return to the ground floor his pulse rate breathing rate and blood pressure are taken and compared with the pulse rate, etc, obtained before the candidate went stair climbing After a rest of three minutes the pulse and blood pressure are again measured The electrocardiograph is then employed and a tracing obtained of the heart s action From all these data the specialists then decide whether the candidate is fit for Class 1 general service at home and abroad Class 2 field service at home Class 3, garrison service, Class 4, labor purposes and sedentary work or is unfit for any army service To make doubly certain of not admitting unfit men, each recruit is separately examined by two specialists

Diphtheria from Cats

An outbreak of diphtheria in an orphanage has been traced to cats Sixty-nine cases which were the great majority of those which occurred came from the boys' house After many investigations and precautions, such factors in the production of the disease as sanitary defects contaminated water supply and food were eliminated Realizing that there must be a carrier of the bacillus, the physician in charge decided to turn his attention to the cats and took swabs from all their throats On bacteriologic examination it was found that the four cats from the boys side of the orphanage were suffering from diphtheria the four cats from the girls' side, although showing other micro-organisms in profusion did not prove to have the true diphtheria bacillus The cats were destroyed and after that only ten more cases of diphtheria occurred They occurred within a few days, showing that the patients had already been infected when the cats were destroyed There have been no cases since

---

Marriages

William Sidney Johnson M D, Carbondale Pa, to Miss Maude Irene Dakin of Washington, D C., June 3

Alfred Dean, M D Grand Forks N D, to Miss Helen LaRue Schurtz of Negaunee, Mich May 24

Harold Ward Stone M D Minneapolis to Miss Frances Carlin Murphy of Faribault Minn, May 15

Lionel Louis Albert M D Malden Mass., to Miss Gertrude Steinmetz of Yonkers, N Y May 22

Horace A Lowe, M D, to Miss Pearl Lines, both of Springfield, Mo, at Monett, Mo May 9

Robert Grier LeConte, M D to Mrs Susan Sturgis Stewart, both of Philadelphia May 24

Martin Henry Merbitz, M D., Chicago, to Miss Norma Helen Irasek of Milwaukee May 17

Hugo Mella M D to Miss Pearl Weed, both of Bismarck, N D, at Minneapolis May 27

Otto Carl Horst, M D, to Miss Rebecca Garrett, both of Springfield, Mo., April 27

George Nye Hiskey M D., to Miss Stella Elizabeth Uthe, both of Chicago, June 3

Deaths

William T S Dodds, M D, Indianapolis, Medical College of Indiana, Indianapolis, 1898, aged 42, a Fellow of the American Medical Association, associate professor of clinical diagnosis in Indiana University School of Medicine, Indianapolis, and professor of bacteriology in the Indiana Dental College, pathologist to the Indianapolis City Hospital and Dispensary and instructor in bacteriology at the Deaconess Hospital, Indianapolis, a specialist in diseases of the chest, who started the tuberculosis clinic movement in Indianapolis and served for two years as deputy coroner of Marion County, died at his home, May 22, from heart disease

Frank Parker Tays Logan, M D, Gloucester, Mass, Harvard Medical School, 1897, aged 49, a Fellow of the American Medical Association and a member of the Association of Military Surgeons of the United States, captain and assistant surgeon, Eighth Massachusetts Infantry, U S V, during the war with Spain, and assistant surgeon of the Eighth Infantry, Mass V M, surgeon on the staff of the Addison Gilbert Hospital, Gloucester, and lecturer on materia medica and therapeutics in the training school of the institution, died at his home, May 26

William Page McIntosh, M D, Surgeon, U S P H S, College of Physicians and Surgeons, Baltimore, 1882, aged 60, a Fellow of the American Medical Association and an active member of the Association of Military Surgeons of the United States, who entered the United States Public Health Service in November, 1885, was promoted to passed assistant surgeon, Nov 1, 1888, and to surgeon, May 20, 1890, and who was placed on waiting orders, April 15, 1915, on account of illness, died at Linwood, Howard County, Md, May 27

John Louis Masters, M D, Indianapolis, Louisville (Ky) Medical College, 1885, aged 56, a Fellow of the American Medical Association and American Academy of Ophthalmology and Oto-Laryngology, a specialist on diseases of the eye, ear, nose and throat, professor of clinical otology, rhinology and laryngology in the Indiana University School of Medicine, a member of the consulting staff of the City Hospital and Deaconess Hospital, Indianapolis, died suddenly at his home, May 25, from cerebral hemorrhage

Francis Barker Davison, M D, Factoryville, Pa, Pennsylvania Medical College, Philadelphia, 1853, aged 88, once president of the Lackawanna County (Pa) Medical Society and a member of the State Medical Society and American Medical Association, surgeon of the One Hundred and Twenty-Fifth Pennsylvania Volunteer Infantry during the Civil War, for thirty-eight years a practitioner of Fleetville, Pa, died at the home of his daughter in Factoryville, April 30, from senile debility

Nathan Jenks, M D, Detroit, Cornell University, New York City, 1899, aged 43, a Fellow of the American Medical Association, associate professor of obstetrics in the Detroit College of Medicine and Surgery, visiting obstetrician to the Women's Hospital and Infants' Home, Detroit, a member of the American Association of Obstetricians and Gynecologists and a fellow of the American College of Surgeons, died in Harper Hospital, Detroit, May 30, three weeks after a surgical operation

Charles Theodore Benner, M D, Tiffin, Ohio, Western Reserve University, Cleveland, 1878, Bellevue Hospital Medical College, 1882, aged 59, formerly a Fellow of the American Medical Association, a member of the Ohio State Medical Association, and once president of the Seneca County Medical Society, local surgeon of the Pennsylvania System, for one term a member of the city council of Tiffin, died in his office in Tiffin, May 23, from angina pectoris

John R McCullough, M D, Chicago, College of Physicians and Surgeons, Chicago, 1883, aged 80, formerly a Fellow of the American Medical Association, a member of the Illinois State Medical Society and Chicago Pathological Society, a practitioner for forty-three years, a veteran of the Civil War in which he served as assistant surgeon of the First Wisconsin Volunteer Infantry, and was a prisoner in Libby Prison, died at his home, May 4

Victor Davis Miller, M D, Mason and Dixon, Pa, Jefferson Medical College, 1861, aged 78, a member of the Medical and Chirurgical Faculty of Maryland, assistant surgeon of the Seventy-Eighth Pennsylvania Volunteer Infantry during the Civil War, coroner of Franklin County from 1864 to 1866, died at his home in Washington County, Md, just across the Franklin County line, May 25, from peritonitis

Lyman Ware, M D, Chicago, Northwestern University Medical School, 1866, University of Pennsylvania, Philadelphia, 1868, aged 74, a Fellow of the American Medical Association and a member of the Chicago Ophthalmological and Otological Society, a specialist on diseases of the eye, hospital steward of the One Hundred and Thirty-Second Illinois Volunteer Infantry during the Civil War, died at his home, June 1, from heart disease

Patrick M Kelly, M D, Kankakee, Ill, Washington University, St Louis, 1892, aged 55, a Fellow of the American Medical Association, for many years a practitioner of Litchfield, Ill, and health commissioner of that city, superintendent of the Kankakee State Hospital from August, 1913, until his resignation a few months ago on account of ill health, died in Colorado Springs, May 30, from nephritis

Walter C Overstreet M D, Sedalia, Mo, Missouri Medical College, St Louis, 1878, Bellevue Hospital Medical College, 1882, aged 58, a Fellow of the American Medical Association, and a member of the National Association of Railway Surgeons, consulting surgeon to the Missouri, Kansas and Texas system, formerly mayor of Sedalia, died in the Punton Sanitarium, Kansas City, May 25

Alonzo Lemuel Leach, M D, Cape May, N J, Jefferson Medical College, 1868, aged 71, formerly a member of the Medical Society of New Jersey, for twenty years a resident of Pennsylvania and surgeon of the First Pennsylvania Infantry, and demonstrator of the Philadelphia School of Anatomy, for several years president of the board of health of Cape May, died at his home, May 25

Clark Wasgatt Davis, M D, Cincinnati, Miami Medical College, Cincinnati, 1886, aged 52, a Fellow of the American Medical Association, medical director of the Union Central Life Insurance Company for many years, health officer of Cincinnati from 1900 to 1906, died at his home, May 25, from heart disease

M Fred Dattelzweig, M D, Chicago, Bennett Medical College, Chicago, 1898, aged 46, a Fellow of the American Medical Association, for many years assistant county physician of Cook County in charge of the North Side division, died at his home, May 30, from heart disease, complicating ptomain poisoning

Marion Delmar Ritchie, M D, Pittsburgh, University of Pennsylvania, Philadelphia, 1899, aged 42, a Fellow of the American Medical Association and a member of the American Academy of Ophthalmology and Oto-Laryngology, laryngologist to the Columbia Hospital, died at his home, May 24

William F Toombs, M D, Springfield, Mo, University of Louisville, Ky, 1880, aged 73, for twenty-five years a practitioner of medicine and later a druggist who moved three years ago to San Antonio on account of his health, died in the Springfield Hospital, May 20, from senile debility

Frederick W Lee, Tiskilwa, Ill, (license, Illinois, years of practice, 1877), aged 81, a practitioner for half a century, a veteran of the Civil War, formerly trustee and president of the village board of Tiskilwa, died at the home of his son in Tiskilwa, May 10

Henry Hardenbergh, M D, Port Jervis, N Y, College of Physicians and Surgeons in the City of New York, 1859, aged 81, vice president of the Barrett Bridge Company and director of the Port Jervis Waterworks Company, died at his home, May 29

Edward A Fox, M D, Cincinnati, Medical College of Ohio, Cincinnati, 1905, aged 34, local surgeon for the Big Four System, county infirmary physician of Hamilton County in 1909 and 1910, died in Bethesda Hospital, Cincinnati, May 6, from septicemia

Charles W Hine, Lonoke, Ark. (license, Arkansas, 1886), aged 71, formerly a Fellow of the American Medical Association, for many years a practitioner and druggist of Stanton, Iowa, died in a hospital in Chicago, May 16, from malignant disease

Willard Herbert Linder, M D, Clinton, Iowa, Marion-Sims College of Medicine, St Louis, 1896, aged 40, formerly of Des Moines and Story City, Iowa, died in the Agatha Hospital, Clinton, May 22, a few hours after an operation for appendicitis

John B Anderson, M D, Chetopa, Kan, Medical College of Ohio, Cincinnati, 1872, aged 68, died at his home, May 18

William H Davis, M D, Corydon, Ind, University of Louisville, Ky, 1882, aged 65, died at his home, May 18

Samuel H Bennett, M D, Mendon, Mich, University of Buffalo, N Y, 1865, aged 79, died at his home, May 14

THE WINE OF CARDUI SUIT

(Continued from page 1810)

May 8, 1916, Morning

TESTIMONY OF DR. R. L THOMAS

The court met pursuant to adjournment Dr R. L Thomas was called as a witness for the defendants

DIRECT EXAMINATION BY MR T J SCOFIELD

Dr R. L Thomas testified that he is a physician practicing in Cincinnati, Ohio He graduated in 1880 from the Eclectic Medical College, of which he is now dean and professor of the practice of medicine He is on the staff of the Seaton Hospital He treats diseases peculiar to women in his general practice, using medicines, local applications etc , he also uses mechanical means, such as pessaries and tampons He has not had any experience with cnicus benedictus or with viburnum prunifolium

There was then asked of the witness a hypothetic question similar to that asked of other witnesses He stated that he did not think that the hypothetic medicine would have any value in the treatment of uterine displacements as it would be impossible for this remedy to restore the ligaments after they were relaxed or to repair the torn perineum He did not think that the hypothetic medicine would be of any value in the treatment of vaginitis or in other forms of pelvic inflammations He stated that most likely it would be harmful by the excitation to renewed activity of the gonococcus by the use of a large quantity of alcohol

There was then read to the witness a quotation from the Home Treatment Book for Women concerning vaginitis The witness stated that it would be impossible for Wine of Cardui to act on the cause of this disease in a curative sense He believes it is not a scientific and specific remedy for this condition

The witness then defined in brief, amenorrhea, dysmenorrhea, menorrhagia and metrorrhagia, all of which are due to pathologic conditions He believed that the hypothetic medicine would be worthless in these conditions He considers the period known as puberty and menopause as normal and physiologic conditions He stated that in his opinion the remedy could not be any good and could not do any good to a physiologic condition and it might possibly do a great deal of harm by overstimulation, by disturbing the digestion or disturbing the nervous system The witness stated that the duration of the menopause is from one to three years and it is not necessarily a critical period in a woman's life He stated certain pathologic conditions which might occur in the menopause and stated that in this sense it was a critical time. He stated that it was very inadvisable to take Wine of Cardui regularly throughout the entire period as recommended in the Home Treatment of Women, page 38, which was read to him

Q—Why do you think that, Doctor? *A*—Well in the first place a great many of these changes do not affect unfavorably and you would be taking a stimulant for a normal condition In the cases that are inclined to be a degeneration you have these conditions as I stated a while ago You may have the degeneration of a malignant growth of the uterus or you may have it of the breasts or you may have it of the ovary and there is nothing in the remedy that I can see that would be efficacious in relieving those conditions

The witness stated that there was nothing in the hypothetic solution which would tend to repel the attack of diseases in the change of life He would object to the taking of the hypothetic medicine during the whole term of pregnancy Unless there was special difficulty, medicine would not only be valueless but might do harm He defined as a misstatement the following quotation from the Home Treatment for Women

> "No one need be afraid of taking Cardui during pregnancy Its action is gentle and strengthening, and it can never do anything but good'

Q—Why do you think it is a misstatement Doctor? *A*—I think a patient that would take a remedy that contained 20 per cent of alcohol for nine months—you might get a disturbance of the digestive apparatus you might get overstimulation, you would get a change in elimination and you would be very apt to get an addiction to the drug or at least there might be—a patient might be led into a desire to take the stimulant constantly

Q—What if any, might or would the effect be in your opinion of such a continued use of an alcoholic solution throughout the period of pregnancy of any of the special organs of the woman s body, that is the organs of elimination? *A*—It would impair the organs of elimination

Q—What would be the effect of it, do you think, if any, upon the kidneys? *A*—The tendency would be to be harmful We find nephritis—when we do find a morbid condition of the pregnant woman —it is very apt to be the kidney In fact, even under normal conditions we have our patients contribute samples every three or four weeks during the pregnant time to see whether there is any tendency to a nephritis which is the most serious lesion of a pregnant woman Alcohol tends towards nephritis to produce it

Q—By alcohol you mean—or by nephritis you mean Bright's Disease what we usually know as Bright s disease? *A*—Bright s disease commonly known as Bright s Disease

Q—I wish to read to you the following quotation, from the Ladies Birthday Almanac of 1909 published by the Chattanooga Medicine Company, and copyrighted by the Chattanooga Medicine Company I read from page 17

> 'Do you suffer from any of these symptoms of female complaints? Headache, backache sideache shoulder pains breast pains, leg, hip or thigh pains bowel pains, drawing pains bearing down pains dragging sensations, falling feelings inability to walk, dizziness numbness, nervousness, fainting spells morning sickness sleeplessness, tired feelings after walking inability to lift weights frequent urination morbid distaste for walking painful menstruation irregular menstruation, unnatural stoppage, too profuse, too often whites flooding weight of bowels straining at stool cramps sterility, general weakness, change of life, hot flashes cold flashes capricious appetite nervous delusions indigestion, loss of appetite sick headache."

Have you an opinion—what is your opinion as to the truth of these various statements?

Mr Walker—You did not give the date of that

Mr T J Scofield—In conclusion on page 17, following what I have just read to you appears the following

> Thousands of ladies who suffer from the above symptoms have obtained relief by taking Cardui, Woman s relief Try it It will help you

Mr Walker—What date was that?

Mr T J Scofield—I am reading from the 1909 almanac, page 17

Q—What is your opinion as to the truthfulness of these statements Doctor? *A*—Well the symptoms that are given there come from such a variety of causes, that it will be impossible for any one remedy or any combination of remedies to relieve all those conditions.

CROSS-EXAMINATION BY MR. HOUGH

Dr Thomas testified that he does not know carduus benedictus or centaurea Cnicus benedictus he stated is a principle of blessed thistle and he has never used it. He has not used carduus marianus to any extent. It is a vegetable remedy recommended for low conditions of the nervous system and atony of the liver It has not to his knowledge been used for dysmenorrhea, amenorrhea or irregular passive uterine hemorrhages His knowledge, he stated, is limited to his own experience. He has not read Ellingwood s Therapeutics on this subject or King's American Dispensatory on this subject. He recommends carduus marianus in one place in his work as a compilation reputed to be used for atony of the liver He does not use it himself at all

Q—Upon what authorities did you base your statement then? *A*—From reading from some prominent authors

Q—What were they? *A*—Of the homeopaths. The homeopaths used carduus marianus for liver troubles some liver troubles partly despondency in liver troubles

Q—Do you know whether there is any difference in action between carduus marianus and carduus benedictus? *A*—No sir I do not know the difference

Q—If the hypothetical question had read carduus marianus instead of cnicus benedictus would your opinion have been the same as you expressed it?

Mr T J Scofield—That is objected to

A—Just the same

Mr T J Scofield —He has already answered it, but the hypothetical question did not say carduus marianus

Mr Hough —I say, if it had said it I am entitled to vary the question to test the knowledge of the witness

The witness knows viburnum prunifolium, which he has used for dysmenorrhea What he has written on the subject is based on his own experience and that of other physicians Dr Thomas does not agree with Ellingwood on all the uses of viburnum He agrees that it is valuable as a uterine sedative in certain conditions

Q —Is viburnum prunifolium good in threatened miscarriage? *A* —In some cases of threatened miscarriage

Q —Is it not particularly indicated in habitual abortion? *A* —In a general way, depending upon the condition, abortion resulting from different conditions

Q —Is it not often efficient in controlling the morning sickness of pregnancy? *A* —Not in my experience

Q —But I am not asking it on your experience alone, but your experience and reading? *A* —That is all I can testify to, my experience in the use of the drugs

Q —No, your experience and reading Your familiarity with the literature on the subject? *A* —Yes, sir

Argument was then made by attorneys concerning the introduction of evidence based on what the physician has read

Q —Is it not a fact that in a number of cases, when given for menstrual irregularities or for the distress induced by uterine displacements in previously sterile females, pregnancy has promptly occurred, proving the influence of the agent in restoring normal functional ovarian activity? *A* —I do not know that it has had that effect

Q —Do you know that it has not had that effect? *A* —No, sir

Q —Is it not a fact that it is the proper treatment of irregular, sudden menstrual flow occurring during repetitions and long continued or violent inflammatory fevers, especially in young ladies? *A* —I did not catch that, the first part of your question

Q —It is the treatment of irregular, sudden menstrual flow, occurring during repetition and long continued or violent inflammatory fevers, especially in young ladies? *A* —No, sir

Q —You say that is not the fact? *A* —Not to my knowledge I never used it for that in that way

Mr Hough —Now I ask leave to read to the witness from Ellingwood on that subject

Mr T J Scofield —I object to that, if the Court please Dr Ellingwood is right over here

The Court —You may read from any book that he has written

Mr Hough —That the witness himself has?

The Court —Yes

Mr Hough —But the witness says he bases his opinion in part on what Ellingwood has written

The Court —As to viburnum prunifolium?

Mr Hough —I understood him so

The Court —He has not said that yet

To which ruling of the Court the plaintiff, etc , excepted

Mr Hough *Q* —Don't you base your opinion in part on what Ellingwood says in his Materia Medica, and Pharmacognosy? *A* —I base it so far as it meets the experience that I have had, certainly

Q —You mean you disagree with them if they state anything different from your own experience? *A* —Not necessarily disagree, no, sir but not necessarily believe all the statements

Q —In what cases have you yourself used viburnum prunifolium? *A* —I have used viburnum prunifolium for the condition where we have as a result of neuralgic conditions irritation resulting in expulsive character of pains, for instance, in dysmenorrhea If there is a sensation of bearing down, as if the patient was trying to pass something, expulsive pain, as an antispasmodic, in that condition Not all conditions of dysmenorrhea do I use it in

Q —How much alcohol was in the preparation which you used under those conditions? *A* —How much alcohol?

Q —Yes *A* —*In the preparation* I used, the specific tincture, it contains about 46 per cent

Q —Forty six per cent of alcohol? *A* —Of alcohol, yes, sir

The witness stated that he has never used senecio aureus It was used by the eclectic school as a uterine tonic It is a vegetable drug It is used in cases of leukorrhea

The witness does not know the amount of alcohol in it

Q —When you have medicines containing alcohol and use them, do you consider that the alcohol has a deleterious effect? *A* —I can not say I use them in that way Not in the way I use them

Q —You mean you can use alcohol with a deleterious effect—that is, your specific medicines, or you can use them with a beneficial effect, can you? *A* —The way that the specifics are used, they are used with a beneficial effect The way they are recommended, the short doses they are recommended in, it would have no deleterious effect

Q —Well, what is the dose recommended of cnicus benedictus? *A* —I do not know

ALCOHOL IN LLOYD'S PREPARATIONS

The witness does not know of Lloyd's cnicus benedictus but he has heard of it The dosage of Lloyd's prunifolium is from 3 to 5 drops in the form of a tincture

Q —Isn't the dosage a teaspoonful every hour or two? *A* —A teaspoonful of the tincture

Q —Of the specific medicine, viburnum prunifolium? *A* —No, sir

Q —(Handing bottle to the witness) Is this the medicine that you use, or that you are referring to? *A* —Yes, sir

Q —It comes in that form? *A* —It comes in that form That is never used a teaspoonful at a dose

Q —What does that say on there on the label? *A* —It says it is a specific medicine, black haw, one dram, which is a teaspoonful, water four ounces, and a teaspoonful of the mixture—

Q —Read what it says on the bottom *A* —Every hour or two A teaspoonful of the mixture, not the—

Q —How much alcohol would there be in the mixture? *A* —Well, there would be a teaspoonful of the mixture in four ounces of water The 46 *per cent* alcohol in four ounces of water and you would get a teaspoonful out of this water

Q —How much alcohol would you get in a day if you took that mixture every hour? *A* —Every hour you would get about ten teaspoonfuls of the mixture, and you would get probably 25 or 30 drops of the medicine in the course of a day, which would include—

Q —Did you say medicine or alcohol? *A* —I said the medicine

Mr Hough *Q* —The dose you say is three to five drops of the specific tincture? *A* —Yes, sir

Q —How does that compare in amount with the amount of viburnum prunifolium in the hypothetical medicine, which was asked about? *A* —It would be much stronger

Q —Which would be much stronger? *A* —The specific tincture

Q —How much stronger? *A* —Well, I would say it would be a great deal stronger

Q —It is just about the same, isn't it? *A* —No, sir, I think not

The witness has not used carduus marianus Most of the medicines which he uses contain alcohol They run from 40 *per cent* up

Q —Now, is the reason that the alcohol that is in the medicine which you use—does not have a bad effect—I say, is the reason that that amount of alcohol is thoroughly oxidized in the system? *A* —No, there is a difference in the preparation of the medicines to begin with

Q —You mean in the percentages of alcohol? *A* —In the percentages of alcohol

Q —Let us take the largest amount which is in any medicine you use? *A* —You take the *specific remedies* as made by Lloyd, and it takes all the percentage of alcohol to extract the virtue of those drugs You take viburnum prunifolium, for instance out of the green bark of the black haw, which is the viburnum prunifolium, it takes 46 per cent to extract all of the virtue of the drug, by that amount of alcohol Twenty per cent of alcohol will not extract it Consequently you are getting more alcohol than you are getting drug

Q —You mean out of the green— *A* —Out of the green bark, and the dry bark has less I think of virtue The dry bark you can buy for 12 cents a pound, and the green bark you pay $1 50 a pound for Lloyd pays $1 50 a pound for every pound of viburnum *he makes*

Q —You mean then, that if a large amount of alcohol *is necessary* to extract the virtues of any herb or drug, that that amount *of alcohol* is not dangerous, provided it is the amount which is necessary to extract the *properties* of the drug? *A* —Provided this is the amount and you use it in the dilution we use it We are not giving this in teaspoonful—

Q —Now take—

Mr T J Scofield —I insist that the witness finish his answer

The Witness —I say, we are not giving this in *teaspoonful* doses of the tincture We are giving the dilution, *which is a very* marked difference If you put a teaspoonful of that tincture in four ounces of water and give a teaspoonful of that, you are getting a very small amount of alcohol, and that alcohol is diluted

Mr Hough *Q* —What is the largest amount *of alcohol* in any drug which you administer yourself? *A* —I do not know the largest amount

Q —What is the largest *amount that you* recollect? *A* —I am not sure, I believe in strophanthus the alcohol is possibly 70 per cent I am not sure

Q —What is the dose? *A* —From *half a teaspoonful to* a teaspoon, to four ounces of water Usually a smaller dose

Q —How frequently? *A* —Generally a smaller dose

Q —How frequently? *A* —Every three or four hours

Q —What is the largest amount of alcohol, measured in *drops*, we will say, which an individual who is taking *medicine* can safely take into the stomach without getting a *deleterious* effect from the alcohol alone? *I am talking now* about one dose *A* —I do not know

Q —Could they take as much as 48 drops of alcohol *diluted* with five times that amount of water, at one dose, without having any deleterious effect from that one dose? *A* —*They* might

Q —And if it had no deleterious effect, there would be no cumulative effect whatever, would there? *A* —From the one dose, *no*

Q —No Then, if they took it three times a day, there would be no *cumulative effect*? *A* —Possibly not—and only took it for one day

Q—Well, if taken through the three to five days of the monthly period it would not have any effect would it? *A*—It is not ever given that long It generally relieves the first day, if it relieves at all

Q—How long is it usually given? *A*—From eight to ten hours the first day, and generally relieves the trouble

Q—Well if it were given through a period of three days it would have no different effect than if it were given through a period of one day? *A*—Possibly not

Q—Isn t it a fact that the specific medicine, black haw or viburnum prunifolium exercises a direct influence over the sympathetic nervous system, preventing reflex irritation especially of the stomach and heart?

Mr T J Scofield—Wait, Doctor that is objected to That is not cross-examination, and if they simply want to test the Doctor s ability—

Mr Hough—It certainly is

Mr T J Scofield—They have gone far enough

Mr Hough—I am talking about viburnum prunifolium

Mr T J Scofield—We are not talking about a specific medicine here

The Court—You may ask him what he gives it for

Mr Hough—I am asking what he knows about the virtues of viburnum prunifolium

The Court—Ask him if he gives it for these various disorders

Mr Hough—It does not make any difference whether he gives it or not if he knows He may know a great deal about a great many medicines that he don't use

The Court—Ask him if he knows whether or not it is used for that purpose.

To which ruling of the Court the plaintiff etc., excepted

Mr Hough—Is it used for that purpose?

Mr T J Scofield—That is objected to

The Court—He may answer

To which ruling of the Court the defendants etc. excepted

Mr T J Scofield—It is not the medicine involved here and it is not material whether some other medicine is given for the same condition or not. We are not investigating that

Mr Walker—He is talking about viburnum prunifolium

Mr T J Scofield—No, he is not He is talking about a different preparation

Mr Hough—I am asking about viburnum prunifolium Is that not true?

A—Acts upon the sympathetic in heart troubles? Is that your question?

Q—On the sympathetic nervous system preventing reflex irritation especially of the stomach and heart? *A*—I have had no experience in that line.

Q—Is it not indicated for that? *A*—It seems to be on the bottle I do not know I never have used it for that purpose

Q—Is it not indicated to correct morning sickness and palpitation during pregnancy? *A*—Some use it for that.

Q—Is it not used to prepare a patient for labor and facilitate a safe uncomplicated and normal labor and especially to prevent post partum hemorrhage? *A*—Some may use it for that.

Q—Is it not used in threatened abortion in dram doses every half hour or so? *A*—No sir not dram doses of the remedy and there are only certain conditions of abortion where it would be. We do not use as a school or as physicians we do not use any one remedy for diseased conditions. For instance abortion there are a number of remedies that could be used for abortion and we use them in special conditions for abortion not all cases of abortion. We claim that there is no one remedy that will cure—that will affect all conditions of any one disease.

Q—You said this is what you used didn t you (referring to contents of bottle heretofore handed to witness)? *A*—Viburnum prunifolium

Q—Now I will ask that you read here what is on that label.

Mr T J Scofield—I object to that, if the Court please

The Court—What is the purpose of this?

Mr Hough—To show—

The Court—This witness has told you what he does Now he says he does use it for certain conditions tending to produce abortion He says he never uses any medicine to correct all the conditions that would produce abortion, any one medicine. Now that was the answer, a perfectly straightforward answer

Mr Hough—As far as it went, it is a perfectly straightforward answer and satisfactory But we are not limited in asking this witness about a certain medicine to things that he has used it for if he knows something about the medicine

The Court—Exactly but what has this bottle to do with it.

Mr Hough—Because he says that what that bottle says is true.

The Witness—Oh no

The Court—No he has not testified to that.

Mr Hough—Do you say that any statement that is on that bottle is not true?

Mr T J Scofield—That is objected to

The Court—Objection sustained He may read that, and then if he relies upon what it says there, and says that it is true, that settles that proposition

To which ruling of the Court the plaintiff, etc. excepted

Mr Hough—Well then, read that and state if you rely on anything that is on there?

The Court—Ask him if he agrees with it

Mr Hough—If you agree with anything that is on there

Mr T J Scofield—There is another reason why I object to that.

The Court—It is just like a book, and I have ruled against quoting from the book

Mr T J Scofield—Excepting that this preparation is not the viburnum prunifolium concerning which the doctor has been inquired of and concerning which Mr Patten testified here that he used

Mr Hough—We will connect that up at another time, and in a different way We are entitled to ask about viburnum prunifolium

Mr T J Scofield—You will certainly not contradict what Mr Patten said about it because Mr Patten told you that he used the viburnum prunifolium from the bark of the limb That is not this preparation

Mr Hough—That has nothing to do with the question at all That is neither here nor there

Mr T J Scofield—Yes, it is right here

Mr Hough *Q*—Will you state that you disagree with the statements on the bottle which you say contains the preparation which you used

Mr T J Scofield—That is objected to

The Court—Objection sustained in that form

To which ruling of the Court the plaintiff etc. excepted

The Court—You might just as well hand him Mr Ellingwood s book and say Mr Witness please be good enough to read that book through and tell me whether you agree with it.'

Mr Hough—If he had told me first that he studied Ellingwood s book and agreed with some of it, and disagreed with the other— I am entitled—

The Court—Has he told you that he agrees with everything on the bottle?

Mr Hough—He has told me that that is the medicine which he uses

The Court—Yes

Mr Hough—And now I am asking him to tell me the conditions for which that medicine is indicated on the bottle, that he disagrees with

The Court—No, you may ask him what conditions mentioned on the bottle he has used it for

To which ruling of the Court the plaintiff etc. excepted

Mr Hough—Or whether he believes in it, or whether he knows it to be a fact

The Court—Supposing he says that he does not believe in it—

Mr Hough—Then that ends it as to that

The Court—Then you cannot put on a witness to prove that this man did believe it.

Mr Hough—If he says that there is something on the bottle that he don t believe in that ends it But if he says he agrees with what is on the bottle—

The Court—Well read it over and see what you agree with I will save the point on that. Mr Patten's testimony however as to viburnum prunifolium, is as Mr Scofield stated it

Mr T J Scofield—Exactly

Mr Hough—Some people use the dry bark, and some use the green Some use the bark from the root, and some the bark from the tree and the pharmacopeias have been changing as to that.

Mr T J Scofield—What does the Chattanooga Medicine Company use?

The Court—If you won t give me a chance to talk now and then we will never get through The difficulty with your position in this case is that it is Wine of Cardui that is under examination and we are interested in what is in that, and what character of viburnum prunifolium is in that Now if that is one kind and this preparation of Lloyd s—this tincture of Lloyd s is another kind—

Mr Hough—That is another matter again your Honor That is not another kind

THE COURT —We will go into that later

Mr Hough —I say I will connect that up later

THE COURT —That is different from what Mr Patten said

Mr Hough —Both come from the same shrub or tree

THE COURT —Just read it over and tell us what you accept and agree with

To which ruling of the Court the defendants, etc , excepted

A —Well, I agree with it in some phases, not all of it

THE COURT —Well, tell us the things that you do agree with *A* —The latter statement, uterine disorders, inducing hysteria, hysterical delusions and petit mal shall be treated with the remedy, if they are due to spasmodic conditions or irritation or nervous conditions

Mr Hough *Q* —You mean to say that that is the only statement on that with which you agree? *A* —That is what I use it for

Q —I asked you whether you agreed with the statements there and asked for you to state which ones you do agree with *A* —I agree with that, that where it is used for that condition, threatened or painful dysmenorrhea, painful affections of the uterus, that occur as a result of nervous irritation, as an antispasmodic, I use it in that condition

Q —You mean then, that you disagree with all the other statements on there?

Mr T J Scofield —That is objected to

Mr Hough —We are entitled to have the witness' attitude correctly defined

THE COURT —He says that is what he agrees with

Mr Hough —I can agree with ten things, and I can say that I agree with Number 1 That don't mean that I disagree with the other nine

THE COURT —If he says he knows nothing about the other nine—

Mr Hough —If he says he knows nothing about the other nine, or says he disagrees with the other nine, then his attitude is clearly defined

Q —Do you agree or disagree with all the rest? *A* —No, sir, I do not know the effect of it on all the rest

Q —How many of the other statements do you agree with?

Mr T J Scofield —That is objected to

Mr Hough —That is perfectly competent

THE COURT —He has told you all he agreed with

Mr Loesch —That is it

Mr Hough —He has told us what he used it for He has not said—

The Witness —I agree with the statement, that it is an antispasmodic for neuralgic conditions in the female, resulting in expulsive pains

Q —Are there any other statements there with which you agree? *A* —No

Mr Hough —Well, that defines it

Mr Hough *Q* —Doctor, you say that Lloyd's Specific Medicine, called viburnum prunifolium, is made out of the green bark? *A* —Out of the green bark

Q —How do you know that? *A* —He told me so

Q —He told you so? *A* —Yes, sir

Q —It is not in any of his literature, is it? *A* —I do not know

Q —Well, you only know from what he told you? *A* —I know that he makes—that there is a marked difference between the virtues of a dried drug and a green drug—

Q —A very marked difference? *A* —I know that Professor Lloyd—that the dried bark, which is practically worthless, he said, can be bought for 12 cents a pound, and the green bark at a dollar and a half a pound, so that there must be a difference, a good deal of difference in the virtue of them

Q —Well, you don't know how it was made, except what he told you? *A* —That is all I know

Mr Hough —I ask that his testimony on that point be stricken out

THE COURT —Well, that would mean to strike out then all of his testimony on viburnum prunifolium

Mr Scofield —They called that out

Mr Hough —I did not call it out, whether it was green or dried

Q —Now, is it not a matter of fact that in the book which they publish, they say that in some cases the green bark is employed, and in other cases the dry bark is employed, and again a bark that is partly dried, and in a few cases a drug is better for age—

Mr Scofield —I object to that—

Mr Hough —and that no rule of thumb is possible in plant pharmacy—

The Witness —Yes

Mr Scofield —I object to the question

THE COURT —Objection sustained

To which ruling of the Court the plaintiff, etc., excepted

Mr Hough *Q* — Well, independent of what Professor Lloyd says about it, don't you know that to be a fact?

Mr T J Scofield —I object to that as immaterial and not cross-examination

Mr Walker —In view of what he just said

Mr Scofield —That is referring to all other drugs We are not interested in other drugs

THE COURT —This man does not pretend to be a druggist

Mr Hough —He has undertaken to inject, when it was not asked for by any question of mine, the statement to the jury that Lloyd used the green bark, and we used a dried bark, and therefore the dried bark was of no account, when, as a matter of fact, he knows nothing about what Lloyd used, except what he says Lloyd told him, and Lloyd's own statements are published and are contradictory of what he says Lloyd told him

The Witness —No, sir—

Mr Scofield —No I object to that statement Lloyd's publications do not contradict what he said

THE COURT —What you read does not contradict it, as to viburnum prunifolium

Mr T J Scofield —No

Mr Hough *Q* —Don't you know that to be a fact—

Mr T J Scofield —I object to that

Mr Hough —That Lloyd—

Mr T J Scofield —Go ahead and ask the question

Mr Hough *Q* —Don't you know it to be a fact that Lloyd's Specifics are sometimes made out of green barks, and sometimes out of dried barks, and sometimes out of partially dried?

Mr Scofield —I object to the question, if the Court please

THE COURT —He may answer that, if he knows

Mr Scofield —I object to it, unless he asks in regard to viburnum, if the Court please Lloyd's Specific is a name that is applied to a very great many different medicines

THE COURT —I am letting him answer because the answer is perfectly harmless, it has nothing to do with this case—a general answer like that

To which ruling of the Court the defendants, etc , excepted.

Mr Hough *Q* —Do you know that that is a fact? *A* —Repeat your question, please

Q —That in many instances dried bark is used, in many instances, and green bark in many instances, and in many instances the partially dried bark? *A* —Yes, sir

Q —And that there is no rule of thumb applicable to that question in plant pharmacy—

The Witness —Yes, but—

THE COURT —In general, there is no rule that will cover all drugs?

The Witness —No rule that will cover all the drugs—certainly not.

Mr Hough *Q* —Now, is it not a fact that the bark of the root, stem and branches of the black haw are medicinal, so the root is preferred by eclectics? *A* —I presume there is virtue in all parts of it, I don't know

Q —Now, is it not a fact that three drops of the Specific Tincture represents three grains of the drug? *A* —Practically, yes

Q —And the dose is from three to five drops of the tincture, is it not? *A* —Yes, diluted, yes, sir

Q —Now, the—is it not a fact that water, or alcohol, extracts the properties of the viburnum prunifolium? *A* —No, sir, water will not extract it

Mr Hough —Now, he has stated that this King's American Dispensary is an authority, and I ask to read the statement of Mr King

Mr Scofield —No, he has not said it was an authority

THE COURT —He did not state that he relied upon it

Mr Hough *Q* —Didn't you say you regarded that as an authority in your school? *A* —No, sir, I did not make that statement

Mr Hough *Q* —Wasn't it, by resolution—

THE COURT —Now, Mr Hough, you may save the point, I don't want you to read this before the jury, because you are getting in indirectly before the jury things that I am unwilling to let you put in directly When you read that resolution—it is very easy to get things into the mind of the jury, and very difficult to get them out

Mr Hough —I was not going to get anything into the minds of the jury—I did not want to get anything into the minds of the jury, I was just going to ask this witness if his school did not adopt this

THE COURT —Suppose the school had?

Mr Hough —And you mean he discards it?

THE COURT —No—he may or may not He says now that he does not rely on it

Mr Hough *Q* —You don't regard it as an authority on this point? *A* —Not now Many things have changed, and that has been out ten or fifteen years That was written years ago Much has been changed

Q —Was there ever a time when water would extract the properties of viburnum prunifolium? *A* —Not all of the properties

Q —Is it not a fact that the leaves of the black haw have been used for tea, made with water only? *A* —I don't know

Q—Isn t that the way it originally started, as a home remedy? A—am sure I don t know

Q—Well, upon what do you base the statement that the properties are extracted only with higher per cent of alcohol than 20 per cent? A—By talking with Professor Lloyd, who has made a study of these plants and the method of extracting the virtues of them, for fifty or sixty years—fifty years I presume

Q—And that is all you know about it? A—Yes, sir, I am not a pharmacist myself

Q—Then as a matter of fact you don t know whether less than 46 per cent. would extract all the properties or not, do you? A—Not personally

Q—When did you talk with Professor Lloyd on the subject? A—Last week.

Q—Last week? A—Yes sir

Q—That is after you knew you were coming up to testify? A—Yes sir

Q—And you talked with him in order to enable you to testify in the case? A—In order to know the amount of alcohol that was in—yes sir

Q—That is a different proposition the amount of alcohol that is in his medicines is stated on the bottle 46 per cent Do you mean to say that Professor Lloyd told you that nothing less than 46 per cent would extract the virtue? A—He stated that they used the smallest amount of alcohol possible to extract the virtues, and maintain it—preserve it—the smallest amount possible in the Specific Tinctures were used to extract the virtues of the root and preserve it

Q—Don t you know as a matter of fact, that the method—that the process of manufacture for their medicines is secret, and nobody but them knows how it is done? A—To some extent

Q—And all you do is buy these bottles in a drug store or write your prescription for them? A—No, sir I know that these Specific Tinctures possess a virtue that many of the remedies under the same name do not possess because they are made differently

Q—I say don t you as a matter of fact— A—Many of them are inert when they are not prepared in that way

Q—You stated that the cnicus benedictus contained 74 per cent alcohol didn t you? A—No sir

Q—Did you say that you knew what it contained? A—No

Q—Did you say you had never seen it? A—No sir

Q—Can you identify this as a bottle of Lloyd s Cnicus Benedictus?

Mr T J Scofield—I object to that, if the Court please That is the same sort of purpose that he is following through this case in reading from the book—

The Court—The objection is sustained because how can he know? The label may say it does, he knows nothing except what he sees on the bottle.

To which ruling of the Court the plaintiff etc. excepted

The witness testified that he could not identify the bottle The witness does not believe that anyone but a physician can buy Lloyd's specific in a drug store The witness knows of Dr J William Fyfe. He has read to some extent Fyfe's book on "Modern Materia Medica and Therapeutics" He has not had the book in mind in giving his testimony It is not a fact that in order to get the most beneficial influence from viburnum prunifolium in cases of threatened abortion, small doses must be given after conception until the fifth month of pregnancy unless certain conditions call for it There might be conditions in which such treatment might be of value.

The amount of the alcohol in the medicine is dangerous in gonorrheal inflammation depending on the quantity of alcohol given The witness does not believe that there is any difference in giving the patient 96 drops of whisky or in giving 48 drops of alcohol in five times that amount of water There might be a difference in the physiologic effect of the two mixtures

The witness then stated that practically all the tonics used by the eclectic school are made up with alcohol Alcohol could not be deleterious in the dosage given.

The witness does not know the amount of alcohol that a person can freely oxidize in the system In the treatment of gonorrhea, the witness does not use drugs in combination with alcohol He uses local treatment. When he uses general treatment, he uses it for general symptoms

The witness stated that only a small percentage of girls need treatment during puberty

He has been called in cases of puberty to give medicine which he gave to correct the conditions which were responsible for the absence of the menstruation. He has given nux vomica, 5 drops to 4 ounces of water three or four times a day, usually only continued for a day He has also given pulsatilla and gelsemium and other specific tinctures

The witness stated that when women have trouble during menstruation they think of taking medicine For hot flashes, he gives pulsatilla, if there is headache, he might give gelsemium, the treatment might be continued for a longer or shorter period of time

The witness has not given alcohol in diabetes and he considers that opinion is divided as to its use as a food The witness stated that the words "female complaints" might include leukorrhea or any of the conditions last mentioned and associated with the female generative organs

All cases of malpositions of the uterus produce uncomfortable symptoms or are accompanied by inflammation Dr Thomas has given drugs during pregnancy to treat constipation for nervous disturbances, etc. Not all of them are given any alcohol

Q—Now when a woman has had a miscarriage previously, and fears a miscarriage at the next conception, what medicine or what treatment do you give them? A—That would depend altogether on her general health If her general health was good I don t know that I would give her any medicine. If her general health was good, I would simply tell her to keep quiet as she approached that time—if she needed any medicine, she would have it If there was any special call for medicine she would have it.

Q—As she approached what time? A—As she—if she had had a miscarriage several times and she was pregnant again, when she approached that time she had it—

Q—That is, the disposition is to miscarry at the same time the tendency is— A—Often it is, yes—the tendency is that, after a few miscarriages

Q—Now suppose her condition was a little run? A—She might have tonics to sharpen the appetite.

Q—How soon would you commence it? A—Whenever that condition was present, whenever she began to complain that her bowels were not moving or her kidneys were not working or the digestion was not good That would precede and accompany the run down condition, and she would be treated for those conditions

During pregnancy he would give natural tonics, fresh air or exercise and medicinal tonics if they were needed The tonics contain alcohol

REDIRECT EXAMINATION BY MR T J SCOFIELD

The witness testified that in each dose of the tonic given there would be about one-tenth of a drop of alcohol

Adjournment was taken until 2 o'clock the same day

May 8, 1916, Afternoon

TESTIMONY OF DR. R. L. THOMAS (*continued*)

The court met pursuant to adjournment

RECROSS-EXAMINATION BY MR. HOUGH

Dr R L. Thomas stated that the largest percentage of alcohol in any medicine which he has ever used would be a dram in 4 ounces, about one-sixth of a drop at a dose He does not prescribe whisky or brandy, and has not prescribed any gin in twenty-five years

TESTIMONY OF MR. J E. KEETON

Mr J E. Keeton was called as a witness for the defendants

DIRECT EXAMINATION BY MR. WALDO

Mr J E. Keeton testified that he is sheriff in Calbert County Alabama He resides in Tuscumbia He has had experience with Wine of Cardui

Q—Now take your own time and in your own way and in your own language state to the court and jury what that experience has been A—Well I had an experience with my wife. I gave it—my wife was taking Wine of Cardui for six years

Q—For six years? A—Yes sir and she had taken it for whites and falling of the womb and irregular monthly periods and she had taken it, she first began to take it about six years ago probably a little more or a little more or a little less than six years ago but right around six years ago she began to take it in doses—from you know a tablespoonful from one to four times a day and she got to increasing the doses on and on and—well she increased the dose and about four years ago we had a miscarriage in our family and she grew worse all the time after that and she then increased the dose until she was taking something like half a tableglassful something like one half of a table glass you know

Mr Keeton stated that his wife had been taking Wine of Cardui before the miscarriage occurred. She had been taking it between four and six *months* After the miscarriage she discontinued for a couple of months and then began taking it again The wife of Mr Keeton is now dead During

ing her illness she saw Dr Greer and Dr Palmer She was not at any time operated on Mr Keeton's wife took between 50 and 100 bottles of Wine of Cardui during six years The witness was asked how his wife happened to begin taking Wine of Cardui

A—Well, she began to read the Ladies' Birthday Almanacs—and besides other older women told her and me both, that was the reason she began taking it.

Mr Walker—I move to strike that out

The Court—Strike out the matter of the advice from older women You saw her read the almanacs? *A*—Yes, sir

Q—And the literature of the Chattanooga Medicine Company? *A*—Yes, sir

Mr Waldo *Q*—How long ago was that, Mr Keeton?

Mr Walker—Your Honor, my objection particularly went to the reading of the literature

The Court—We will strike out of the record the witness' conclusion, that that is why she began The fact that she read the literature of the plaintiff company may stand

Mr Walker—Yes, and the fact that she talked with older women, which is his conclusion as to the reason why, that it was the result of that

The Court—That is stricken out

Mr Walker—And the other stands, I take it?

The Court—Yes

Mr Walker—All right

Mr Waldo *Q*—Do you say that you and your wife read the Ladies' Birthday Almanac together? *A*—Yes, sir

Q—How long after that reading did she begin the taking of Wine of Cardui? *A*—Oh, I could not say, right after that.

Q—Did she take it continuously from that time on, or only at periods? *A*—Off and on, you know She did not take it regularly, just owing to her feelings, you know

Q—Up to within what time of her death did she continue to take Wine of Cardui? *A*—I could not hardly say probably two months

Q—How long has she been dead? *A*—Since the 23d of January

CROSS-EXAMINATION BY MR. WALKER

On cross-examination Mr Keeton stated that he and his wife read the Ladies' Birthday Almanac almost every year He knew of two women with whom his wife talked who advised her to take Wine of Cardui He was present when she talked with the women They told her it was good medicine for female troubles Mrs Keeton was 38 years old when she died and 19 when she married She had been suffering for almost a year before she began to take Wine of Cardui This was between five or six years ago She first began complaining of female trouble when 25 and would have a doctor when she needed him Drs Palmer and Greer were their family physicians and attended Mrs Keeton just before her death Mrs Keeton would not have trouble at every menstrual period The Wine of Cardui was purchased from Drisdoll's drug store in Tuscumbia Some was bought from the Palace drug store The witness bought Wine of Cardui in six bottle lots He does not know how long it would last. The last time he purchased it before his wife's death was in October He bought either two or three bottles He does not know how many were left after she died The duration of his wife's last illness was six months Her trouble was cancer of the womb This last answer was brought out after a statement by the Court to the effect that he wished to correct the ruling made on direct examination, namely a man is entitled to tell as a matter of family history what the matter with his wife was and he may tell how long her last illness was and what she died of

REDIRECT EXAMINATION BY MR WALDO

Mr Waldo asked the witness for what condition Mrs Keeton saw Drs Palmer and Greer Objection was made to the question and sustained

TESTIMONY OF DR WILLIAM HENRY GREER

Dr Greer was called as witness for the defendants

DIRECT EXAMINATION BY MR. WALDO

Dr Greer testified that he resides in New Decatur, Ala He has been practicing medicine sixteen years He graduated from Grant University, Chattanooga, Tenn He has been practicing medicine in Alabama all the time since he graduated with the exception of one year in Oklahoma

The witness had had experience with Wine of Cardui in his practice The first case was a girl, Miss A I, 15 years old 'She was suffering from amenorrhea and had been taking Wine of Cardui for two years without relief She was suffering intense pain in the abdomen and had ecchymotic spots all over her body She had convulsions He found atresia of the vagina and made an opening into the womb and relieved her temporarily until she could be taken to the hospital and operated on, and on opening the abdomen the uterus was found enlarged and filled with blood One tube and ovary were removed and the patient made a good recovery

THE CASE OF MRS KEETON

The next case was that of Mrs Keeton, wife of the previous witness

A—I saw Mrs Keeton off and on for the last six years, that is to say, I would be called into the family, to see some other member of the family—other members of the family

Mr Loesch—The witness is suffering from a throat affection

The Witness—I am sorry to put you to all this trouble. I will say that it is about two years and a half ago Mrs Keeton called my attention to her menstrual disturbances and I told her, I said, "Well,' I said, 'Probably you had better come to the office or I will examine you here at home and we will see what this trouble is" She said she had been troubled for several years She said, "Well," she said, "The boy is sick now, and we will wait. I am taking Wine of Cardui, and I will see what it does for me" Well, I did not press the matter

At other times she mentioned it to me, probably at some neighbor's house, or something was said and she was coming to have a treatment She did not do it.

About eight months ago they called me to the home and I made an examination, an instrumental examination and I found a cancer of the cervix, probably the beginning of a cancer of the cervix, and I advised an immediate operation She refused and persisted in taking Wine of Cardui Doctor was called in and made an examination, and either went with her or sent her to Memphis, where Dr G M Holder made the same diagnosis and told her that he could not do anything for her It called for an operation That was probably five or six weeks after I saw her She returned to her home, and I went from Decatur down there several times to see her and she died in January of carcinoma of the uterus

Mr Waldo—That is—carcinoma of the uterus?

The Court—I cannot understand whether there was an operation performed

The Witness—No, sir, nobody would touch it.

Mr Waldo *Q*—Why wasn't there an operation performed? *A*—Well, she seemed to have faith in this medicine, that she was taking

Mr Walker—I move to strike that out

The Court—Strike it out

To which ruling of the Court the defendants, etc, excepted

Mr Waldo *Q*—I mean this, Doctor— *A*—I answered that question previously that it was at an operable stage, before

The next case was that of Mrs J E W, who said she had taken considerable Wine of Cardui She had two or three miscarriages and he did curettement after each miscarriage

The daughter of Mrs J E W—— developed chorea When she consulted the doctor he advised her to quit taking Wine of Cardui, gave her tonics, advised rest in bed, gave her a diet and laxatives and she became well

Q—Now, have you another case, Doctor, that you remember of? *A*—I have plenty of cases, but the next one I would give you is Mrs W—— G—— I have her word for it, I have this as part of the clinical history of the case She came to me after she had had an operation in Birmingham She was very nervous and very much run down and she was suffering considerable pain in the abdomen

From my examination I found that her abdominal contents were sagging very low and I inquired—she looked like an alcoholic and she said, "Yes," she says, "I drink some whisky" I found that she had been a sufferer for many years She was a widow at that time and after she had married her husband had had her operated on She said that she had had this female trouble a long time She took this Wine of Cardui and took some whisky with it

Mr Walker—Took some whisky along with it? *A*—Yes, I considered her an alcoholic case probably brought on from—

Mr Walker—That is objected to

The Witness—From the use of this medicine

Mr Walker—I move that that be stricken out

Mr Waldo—Just state what you know of the case, from your own experience with the case

Mr Walker—That is out then?

The Witness—Well, from the history, from the history she gave and from my observation, I considered it such a case

Mr Waldo *Q*—How long had she been taking Wine of Cardui? *A*—I could not tell you.

Q—She did not say? *A*—No, sir

Q—What became of her, doctor? *A*—Well, I had—I put her on some tonic and put an abdominal supporter or binder, a strong binder on her and rested her up in bed about a month, and she improved I do not know to what extent But she improved materially She quit her habit.

Q—Is that all the experience you have had with Wine of Cardui in your practice? *A*—No, sir that is not all the experience I have had

Q—Do you care to tell any other experience? *A*—Well, I do not think it would be necessary

CROSS-EXAMINATION BY MR WALKER

On cross-examination, the witness gave in detail the names and residences of the patients mentioned on direct examination He described in detail the various points mentioned in the direct examination

In the case of Mrs G——, to whom he gave tonics, he gave strychnin arsenic, hypophosphites and phosferrol The witness testified that he came to Chicago about April 22, stayed three days and went home, stayed home three or four days and then came back to Chicago He first saw Mr Keeton in Chicago on May 7 He, himself, spoke to Mr Keeton about testifying for the American Medical Association The witness belongs to his county and state societies and to the American Medical Association He has had The Journal ever since he graduated He read the articles on Wine of Cardui He received a letter from Dr Perry, secretary of the state association He first met Dr Heizer about two years ago in Sheffield, Ala He had not received any communication from the American Medical Association asking him to help defend this suit

Q—When did you first know that the American Medical Association had been sued as a result of the articles that they published against Wine of Cardui? *A*—When I realized it fully was when Miss Ervine came to my office asking—

Mr Walker—I am just asking you for a date

Mr Waldo—Let the witness answer

Mr Loesch—He has a perfect right—

Mr Walker—I called for a time I asked him when and he started to tell me

Mr Loesch—He started to fix the time by your woman detective coming around

Mr Walker—Oh, now here here

The Court—When calls for a date

Mr Walker—Yes It don t call for anything else

Mr Waldo—If that is the only way he can fix the date I think he has a right to say it

Mr Walker—If he cannot tell the date he can tell me so (Addressing Mr Waldo), Pardon me for being in front of you

Mr Waldo—Excuse me for being behind you

Mr Walker—Oh that is all right that is where I like to have you What I would like to ask you Mr Juror—or Mr Witness—is for the date *A*—I could not give you any date

REDIRECT EXAMINATION BY MR WALDO

Q—From whom did you first learn—I withdraw that By whom were you first approached to become a witness in this ca e?

Mr Walker—That is objected to

The Court—He may answer

To which ruling of the Court the plaintiff etc excepted

A—Well—

The Court—That calls for somebody s name *A*—Now I modify my answer in the way—

Mr Walker—You see approached to become a witness.

Mr Waldo—In this case

Mr Walker—That calls for something that somebody said to him It assumes from their own witness that he was approached by somebody to become a witness

The Court—You brought that out in a way in your question about Mr Heizer "When did you first hear about this case?'

Mr Walker—And that is on cross-examination

Mr Loesch—Why—

Mr Walker—I have a right to assume on cross-examination but I do not understand that they have, with their own witness

Mr Waldo—They brought out the fact that their own emissary had been down to see this witness before he had seen Mr Heizer

The Court—What difference does it make gentlemen?

(Witness excused)

TESTIMONY OF DR. EDMUND WEARING SIMMONS

Dr Edmund Wearing Simmons was called as a witness for the defendants

DIRECT EXAMINATION BY MR WALDO

Dr E W Simmons testified that he is a physician practicing in Summerville, S C., and a graduate of the Medical College of South Carolina and has been in practice eleven or twelve years He has had some experience with Wine of Cardui

Mr Waldo *Q*—Doctor will kindly state to the jury what that experience has been? *A*—Well the first case I was called to see a woman who was supposed to have taken morphin She was about six miles from Summerville and when I got there I found on examination that the woman was practically under the influence of alcohol acute alcoholism I then administered a hypodermic of apomorphin and caused her to vomit and when I did so her husband, who was very much worried before, said Just a common drunk

Mr Loesch—We will have to withdraw the witness if he cannot do better than that

Mr Walker—I think it is more dialect than the voice

Mr Waldo—We have no dialect in the South, sir

Mr Walker—Well, it is something very much like it

The Court—Talk louder and slower so that everybody will be able to hear you

Mr Walker—I think he is talking French

Mr Waldo—Go ahead, and try to enunciate distinctly *A*—He simply said plain drunk and went out of the room I inquired what she had taken and I found she had not any whisky there but there was a bottle on a shelf near the bed it was a bottle of Wine of Cardui I asked her if she had been taking it after about an hour and a half or so—if she had been taking this

Mr Walker—That is objected to

Mr Waldo—He says that it was an hour or two afterwards that he asked her

The Witness—I asked her what she had taken and she said she had taken this about two thirds of the bottle—about two thirds of the bottle had been used

Q—Two thirds of the bottle? *A*—Two thirds was empty and one third was in the bottle One third was in the bottle on a shelf near the bed

Q—Of what? *A*—Wine of Cardui

Q—Go ahead *A*—I asked her if she had been taking that all the time and she said she had been taking it for—about six months and in regard to this she said that the usual dose was about a tablespoonful but she had gradually taken it in larger amounts just from the bottle no particular amounts and that she had taken that probably that same day *two thirds of the bottle within a few hours probably*

Mr Walker—He says that she probably had taken it—

The Court—Strike out the probabilities Mr Reporter Did she tell you on that occasion how much she had taken? *A*—No she did not sir

Mr Waldo *Q*—Didn t tell you how much she had taken out of that bottle? *A*—No sir Only what I saw in that bottle—just taken that day

Q—She told you she had taken all except what was in the bottle that day? *A*—Practically, yes

Q—What became of that woman? *A*—That was the last I saw of her She was just a transient when I saw her and I have not seen anything further of her

Q—Have you had any other experience? *A*—The case of a child about thirteen years old a case of amenorrhea I was called to see her and she was suffering from cramps She had had a certain period but she never had menstruated they never had appeared That was a case practically of hookworm She had been taking Wine of Cardui for them and I asked her if she had taken Wine of Cardui and she had at these periods I gave her the hookworm treatment and in the course of a few months the periods were established That is practically all the experience I have had

Q—How long had she been taking Wine of Cardui?

Mr Walker—That is objected to

A—Probably—

The Court—What did she tell you? *A*—Her mother told me about a year a year to eighteen months a year to eighteen months

Mr Waldo *Q*—What became of that patient? *A*—She got all right

Q—Is that the limit of your experience with Wine of Cardui? *A*—Practically the limit yes sir

CROSS-EXAMINATION BY MR WALKER

The witness testified that he commenced practice immediately after graduation He sees practically 50 or 100 cases of menstrual disturbances in women and perhaps one third of these are young girls at puberty

The first case he treated in 1910 The family were transients working temporarily on a farm They live in a little hut There was one child in the family The woman was about 28 or 30 and did not have hookworm so far as he knew The woman was under the influence of alcohol He understood from the woman that she had taken Wine of Cardui that day He saw her about 10 o'clock at night He did not notice that there was a whisky jug in the hut and the patient told him there was none The witness testified in detail concerning the operation of the patient He was then cross-examined in detail concerning the case of the child with amenorrhea

The witness testified that he came to Chicago at the request of Dr Heizer after he received a communication from Dr Hoyne, secretary of the state medical society The witness came to Chicago on April 25 and left the day after Mr Patten's death He returned on Thursday night previous to testifying The witness has heard of Wine of Cardui being used in menstrual disturbances all during his practice

TESTIMONY OF DR J G VANCE

Dr J G Vance was called as a witness for the defendants

DIRECT EXAMINATION BY MR WALDO

Dr Vance testified that he resides in Marvel, Ala He graduated from the Birmingham Medical College in 1905 He practiced two years in Warrior, Ala, and later at Marvel He has had experience with Wine of Cardui in his practice In reciting the history of his cases he referred to notes

His first case was Mrs D H, a white woman, aged 40, suffering from hemorrhages at menstruation periods She had a laceration of the perineum and a prolapse of the womb and she had four living children and had had eight miscarriages She had received medical attention at each miscarriage The patient stated that she had taken some six bottles of Wine of Cardui without relief He saw her in 1914

The Witness —The next is Miss Ira H—— I will give you these names after I get down from the stand White, age 34, pellagra, my diagnosis I was called during the fall of 1913 to see this woman Her mother gave the history of her having a hemorrhage at each menstrual period, her menses staying all the way from ten days to two and three weeks She had been menstruating at this rate between two and three years

I examined her I did not make a digital examination I noticed the redness of her hands and forearm After that I got her history, a history with reference to a sore mouth and upset stomach I made a diagnosis of pellagra, and put her on the treatment accordingly At that time we did not know very much about the diet treatment of pellagra, but I put her on a nourishing diet because I felt that that was the thing to do In addition to that, I put her on the arsenic

This woman made a recovery Today she is not having any hemorrhages at her menstrual period, and since Dr Goldberger's theory came out with reference to diet, of course, I put her on forced diet, and she has improved She is not a well woman, because her financial condition—her mother's financial condition is such that they cannot get nourishing food and a proper diet

Mr Waldo *Q* —Well, doctor, in that case did Wine of Cardui form any part of the clinical history which you got from her? *A* —It did

Q —What part did it form? *A* —Her mother got a bottle for her, and she took three doses, and it made her so dizzy—well as she said, expressed it, it just made her drunk, so her mother told her not to take it.

Now, I will give you another—

Q —Did she take any more, Doctor? Do you know? *A* —Just the three doses She took it all in one day

The next case was Mrs J B——, a white woman, aged 35, he saw in 1914 She complained of pain in the lower part of the abdomen at the time of the menses She had practically the same symptoms as those of her sister, the previous case, although she was better nourished She had taken some three or four bottles of Wine of Cardui consecutively for pain in the abdomen She, like her sister, stated that it stimulated her and made her face feel flushed and made her dizzy She said that she seemed to forget that she had the pain around While he did not make a positive diagnosis, symptoms showed that she had pellagra, and he put her on forced feeding

The next patient was L W——, colored, aged 35, whom he saw in 1915 She suffered with pain in the region of the appendix and ovaries at the menstrual periods On examination he found a mass on the left side and a smaller mass on the right side and he told her that he thought she had a fibroid tumor She went to a hospital and was operated on She gave a history of having taken seventeen bottles of Wine of Cardui without any relief over a period of a year The patient is well today and working in a camp at Marvel, Ala

The next case is M K, colored, aged 36, whom he saw in 1908 She complained of flooding and of pain on both sides during the menstrual period On examination, he was convinced that she had pus tubes and advised operation The patient was operated on in 1912, both tubes and both ovaries being removed She had taken six bottles of Wine of Cardui without relief

The Witness —I asked her if she had taken any medicine, and she said she had taken this Wine of Cardui, six bottles When I asked her if she had taken anything else, she said yes, she took whisky when she could get it, but her husband did not like to have her take whisky, she said, and took this Wine of Cardui, because she got practically the same benefit from taking Wine of Cardui as she did from the whisky This woman, as I said, was operated on in 1912, and she is a well woman today, doing her own work

The next case is Mattie D——, colored, aged 30 I doubted that age, but she gave me that as her age, and I, of course, had to put it down

Mr Waldo *Q* —How old did you think she was? *A* —She looked to me to be about 36 or 38, but you cannot tell much about a nigger's age, I will be frank with you there.

I saw this woman in 1914 She gave me a history of smothering, and especially did she give that history of smothering if she ate anything after four or five o'clock in the afternoon Her food, she said did not seem to sit, and it lay very heavily on her stomach In questioning her with reference to taking medicine, she said that she had taken nothing other than Wine of Cardui, except an occasional bottle of some form of pepsin I believe it is syrup of pepsin—but I am not positive Anyhow, it is bought in any drug store. It is just a laxative with some pepsin in it.

She had taken this Wine of Cardui for a period of eight years, if I am not mistaken—I think I have that down Yes, a period of eight years, and no relief other than a very happy feeling when she would take this Wine of Cardui

She gave a suspicious history of possibly syphilis, so I sent her to St Vincent's Hospital and had a Wassermann reaction made for syphilis, and it was positive, plus 4 She was given intravenous injection of salvarsan with follow up treatment of mercury This woman returned to our place, and she is living there, and from a woman of about 130 pounds, she weighs about 180 pounds at the present time She has no trouble to amount to anything with her digestion at the present time

I do not know whether this would be worth anything or not but the intern at the hospital told me that—

Q —Never mind what the intern told you. *A* —Well, it is all right then

Q —You said you sent her to St. Vincent's Hospital? *A* —St. Vincent's Hospital, Birmingham, Ala

Q —That is over on Red Mountain? *A* —Yes, in Birmingham

The next case was Mrs G R——, white, aged 31, whom the witness saw in 1911 She had flooding at every menstrual period since 1906 She was advised by a wandering herb doctor to take Wine of Cardui, which she took without relief She had taken three and a half bottles over a period of eighteen months

The next case was R W——, colored, aged 35, whom he saw in 1915 From the symptoms, and examination, he diagnosed tuberculosis The patient had taken Wine of Cardui She had read one of the Wine of Cardui books and stated after reading this she thought that she had had everything in there and that the medicine would cure her

The next case was L H——, now dead, whom he saw in 1913, She told him that she had been menstruating for over two weeks and was wasting away He examined her and found a cauliflower-like growth on the mouth of the cervix, and suspected cancer The patient stated that she had taken six bottles of Wine of Cardui She went to the hospital and was operated on A microscopic examination showed cancer The patient lived nine months after she was operated on

The next case is A F——, a negro, aged 41, complaining of pain in the lower part of the abdomen There was distention of the abdomen and cessation of her menses of about three or four months The witness saw her in 1915 On examination he found a growth on the left side, also one on the right The patient was operated on for the removal of a pus tube on one side and a fibroid tumor on the other The patient gave a history of having taken three and one half bottles of Wine of Cardui without relief

The next case was Mrs H B, whom he saw in 1905 She had been confined five or six months previously At the time of confinement she had had fifteen convulsions During pregnancy she had taken Wine of Cardui, as it had been recommended to her to make her pregnancy easier She had taken it three or four months prior to the birth of the child, and she also took some after the birth of the child On examination he found a complete laceration of the perineum She went to Birmingham and was operated on In 1907 she was again confined, although this time she had taken no medicine other than laxatives She had an entirely normal delivery

The next case was a Mrs M H, a sister of this patient whom he saw in 1907

The Witness —Mrs M—— H—— On the morning that I confined Mrs H—— B—— I received a call to the commissary of the

Sibley Brothers Coal Company at Warrior to come there quickly as a woman had fainted in the store When I arrived I found this woman lying on the floor She was unconscious and did not know anything I recognized her, knew where she lived and called a buggy and sent her home.

I left treatment for this woman I recognized her condition as being serious as she was bordering on puerperal convulsions I left her and returned to my home On arrival at my home I had a call from this woman s sister Mrs H—— B—— whose case I have just gave and went there to confinement. While I was at Mrs H—— B——s I got another call to come back to Mrs M—— H—— I could not go and another physician went and confined Mrs. M—— H——

Mrs M—— H—— died I saw her about two hours after her death she was jaundiced very much swollen her feet and legs were swollen her face and hands were swollen she died in convulsions

Mr Waldo Q—Now did Wine of Cardui constitute any part of the clinical history of Mrs M—— H——? *A*—I only know what her sister——

Mr Walker—I object to it

The Court—You were sent for by the sister?

The Witness—No I was sent—

Mr Walker—He found her in the store and she was sent home, and then he went to the sister's house and was sent for from there by Mrs M H——

The Court—Well if he got the information from any member of the family during the time he was treating the patient I would say that he could give that history, but if he received it at some other time why then it must necessarily come within the hearsay rule.

The Witness—Well I received this—your Honor I received this information about two hours after I visited this woman from her sister

The Court—Well, she was still alive?

The Witness—Yes.

The Court—And the information was given you for the purpose of enabling you to treat her?

The Witness—I asked her if she had received any treatment from any one at all and she said—

Mr Walker—I object to that.

The Court—Yes tell just what she said about Wine of Cardui

The Witness—She said she had taken some Wine of Cardui that is all the treatment she had received.

Mr Hough—Well the sister s statement is hearsay She would not be competent to testify

Mr Walker—He never went to treat this woman, he found this woman in a store

Mr T J Scofield—He gave her treatment.

Mr Walker—No no

Mr Hough—It is not competent but let it go

The Court—He never had an opportunity to treat her As a matter of fact the sister saying she had taken the Wine of Cardui not knowing when and what amounts the testimony is negligible anyway It may be stricken out

To which ruling of the Court, the defendants etc. excepted

The next case was that of Mrs J O—— whom he saw in 1908 a confinement case The woman stated that she had had difficulty in carrying the child. She had received no other treatment than the taking of Wine of Cardui He advised operation which she did not have and the last heard of she was still in the same condition.

The next case was H G B a man whom he was called to see in 1908

The Witness—H G B—— His residence was at that time in Birmingham. I was called *in 1908 to see this man* who wanted me to give him something to stimulate him brace him up so that he could go to work. He was a painter under contract painting the houses for the Roden Coal Company at Marvel Ala. at that time It had been several days since he had been at work and he wanted something to brace him up so that he could go back to work.

I asked him what he had been taking and he said he had been taking whisky When he could not get whisky he would take Wine of Cardui.

Mr Walker—I move to strike it out.

Mr Waldo Q—Did you ascertain how much Wine of Cardui he had taken doctor? *A*—I did not.

Mr Walker—Wait a minute. He had not been taking any then He had been taking whisky He had been taking whisky I move to strike it out.

Mr Waldo—We will find out on this particular case. Q—Did he state whether he had been taking Wine of Cardui or whisky? *A*—Well I could not say at that particular period. He told me that he had taken Wine of Cardui but he did not tell me at that period. He said—well at that time, we were supposed to be dry especially in that county

Mr Waldo—What county in Alabama? *A*—Bibb County

Q—Bibb County? *A*—It was pretty hard to get whisky—

Mr Walker—I object to that, unless the man told you, and then it would not be competent.

Mr Waldo Q—Did you see this man at Birmingham? *A*—I have seen him in Birmingham

Q—But on this occasion when he was suffering from— *A*—I saw him at Marvel Bibb County Alabama

Q—Did he state at that time whether part of the spree had consisted of drinking Cardui? *A*—He did not

Mr Walker—That is objected to

Mr Waldo—He said he did not, you ought to be satisfied

Mr Walker—Well, he answered over my objection, and I don't know why that should make me content

The Court—Go ahead please, we are going to stop in a few minutes

The next case was J W G——, whom he saw in 1910

The Witness—Mrs J W G—— I was called to see her in 1910 I cannot say just exactly when in 1910 I saw her but when I reached her I found her rolling and tossing from one side of the bed to the other in a very filthy condition had been spitting on herself and she resembled a woman who had been on a drunk

I could get no history from the woman because she was in such a muddled condition that she could not give any account of herself

On inquiry from her husband as to what she had taken he produced a bottle of Wine of Cardui and he said she had taken that

Mr Walker—I object to that

The Court—This was at the time when you called?

The Witness—At the time your Honor

The Court—Was the bottle empty, or did it have the medicine in it?

The Witness—Just about half—half full

The Court—Very well

To which ruling of the Court the plaintiff etc. excepted

Mr Waldo Q—Is that all of your cases doctor? *A*—One other case

Q—Let us have it. *A*—Mrs M J S—— I saw this woman in 1910

Q—Go ahead Doctor *A*—I saw this woman in 1910 and she was drunk When *I went in the room* she was *standing upon the floor* had a bottle of Wine of Cardui in her hands and just as I went in the door she drank some Wine of Cardui out of the bottle I only saw this woman drink Wine of Cardui this one time I do not know whether she became drunk from drinking this Wine *of* Cardui or not I do know that she had been drunk at different periods during her residence at that place

Q—Did you say you saw her drink the Wine of Cardui out of the bottle? *A*—I did

Q—How *much did she take?* *A*—Well *I really could not say* She —from the time I walked in the door—I walked up to her a distance of about I suppose eight or maybe ten feet she kept the bottle to her lips from the time I walked from the door to her She drank two or three pretty healthy swallows.

Q—You had been called there to treat her professionally? *A*—I was treating her at that time and merely called to see her

Whereupon an adjournment was taken until Tuesday, May 9 1916 at 10 30 o clock a m

May 9, 1916, Morning

TESTIMONY OF DR. J G VANCE (*continued*)

The Court met pursuant to adjournment Dr J G Vance resumed the stand for the defendants

CROSS-EXAMINATION BY MR. HOUGH

In the absence of Mr Walker, cross-examination of Dr Vance was undertaken by Mr Hough

Dr Vance testified that he is a company physician for the Roden Coal Company at Marvel, Ala and is paid by assessments on the employees When he was in Warrior Alabama he was employed by two brick yards and three coal companies He testified that he is a member of the American Medical Association He received a letter from Dr Perry secretary of the state medical society, and also had a letter from Dr Heizer before he saw him

Dr Vance came to Chicago first on the 24th of April He went home when the Court adjourned and returned later When he wrote to the secretary of the state medical society he told of three cases He did this without reference to his records Dr Vance then gave in detail the names and addresses of the patients described in the direct testimony Practically all of his testimony was taken from the records of his cases It was understood that the expenses were to be paid and that he received a per diem but this is not dependent on the number of cases concerning which he testifies

The witness was then questioned in detail concerning the incidents described in the direct testimony He was asked in minute detail concerning the symptoms of the various patients He does not keep a record of all his cases but only of those which are interesting

The witness was then cross-examined in detail concerning each of the patients, as to the time he saw them and the statements made by the patients concerning Wine of Cardui, also the subsequent history of each patient

TESTIMONY OF DR TORALD SOLLMANN

Dr Sollmann was called as a witness for the defendants

DIRECT EXAMINATION BY MR T J SCOFIELD

Dr Sollmann testified that he is a physician He graduated in 1896 at the Western Reserve University, Medical Department, Cleveland, Ohio He is a professor of pharmacology, and materia medica at the Medical Department of Western Reserve University, and also professor of Materia Medica at the Cleveland School of Pharmacy He has taught continuously in the Western Reserve since 1895, the first two years in physiology and afterward in pharmacology

Q—Are you a member of any scientific societies? *A*—Yes, I am a member of the Cleveland Academy of Medicine, Ohio State Medical Society, American Medical Association, American Association of Physicians, the American Pharmaceutical Association, the American Physiological Society, American Biochemical Society, American Society of Pharmacology and Experimental Therapeutics, and the Society for Experimental Biology and Medicine

Q—Since you have been connected with these various societies, have you held any official positions with them, or any of them? *A*—Yes I have been president of the Pharmacological Society, I have been the chairman of the Section of Pharmacology and Therapeutics of the American Medical Association, I am a member of its Council on Pharmacy and Chemistry, and chairman of the Committee on Therapeutic Research of the Council I am a member of the Pharmacopeial Revision Committee, of its executive committee—of its Committee on Scope, and chairman of its Committee on Therapeutics and Pharmacodynamics

Q—Doctor, have you published any original investigations in pharmacology? *A*—Yes From my laboratory there have been published approximately, I should say, about two hundred pieces of scientific work, and in the most—most of those, I either did myself or was in direction of them—directed them

PHARMACOLOGY

Q—Define the term "pharmacology," so that the jury may understand what is meant by it, Doctor—and ourselves as well *A*—Pharmacology deals with and investigates the actions of drugs on living organisms, and that includes portions—involves a knowledge of chemistry, or pharmacy, of physiology and the principles of the treatment of disease—scientific principles of the treatment of disease

Q—You say it involves the *action of drugs on the living organisms* Now, what do you mean by that, living organisms—so that we may understand? *A*—That means anything that has life in it

Q—Yes? *A*—Of course as it is used, it—that is by members of the medical profession, it relates mainly—eventually at least to the effects on man and on the higher animals

Q—Then, if I understand you, that includes both human beings and the higher animals? *A*—Yes, incidentally *also lower animals*, but that is the main thing

Q—Also lower animals? *A*—Yes.

INVESTIGATING A REMEDY

Q—Doctor, you said that pharmacology is concerned in investigating the action of drugs Now, assume that a certain preparation, which we will call Wine of Cardui, is claimed to be a female tonic, and a scientific remedy against various diseases of the female generative organs Will you explain to the jury how the action or value of such a preparation might be determined? *A*—The real investigation *of the action or value* of such a medicine would have to be determined by the ordinary methods of pharmacological science That would include an investigation of the composition of such a remedy—an investigation of its effect upon animals, and a clinical investigation

Q—Now, what would be the clinical investigation—what would the clinical investigation involve? *A*—You say the clinical investigation?

Q—Yes *A*—The clinical investigation would be the determination of its effects *on* patients in hospitals—preferably at least

tion –Now, in order to obtain proper and definite results from such
the right what is it necessary to do to avoid complications and
fibroid tumor q? *A*—Before taking up such an investigation on
She gave a history c to make, as I said, a valuable investigation, one
of Cardui without an it, as I pointed out before, by investigating
patient is well today a of such a drug, and its effect upon animals
een done that it would be desirable to test
The next case is M hall Then, having laid a foundation for its
1908 She compla ed o ceed to make such tests—*having assured*
during the menstrual pe *harm—he could then proceed to make*
vinced that she had pus ld be—especially when they were based
patient was operated on and ation—they would have value
being removed She had a chemical investigation be necessary
Cardui without relief tion? *A*—A chemical investigation, I
he first step, because the first thing

that an investigator would want to know, when he is trying a drug is what he is really dealing with, the sort of a thing that he has in his hand. He can go at his *investigation* with very much better understanding in a case of that kind than if he takes a thing that he has absolutely no idea what it may contain, or what it may not *contain*

Very often, if he knows what is in a *mixture, he* will know the particular direction of his investigation, the direction that his investigation ought to take, instead of having to feel his ways in a thousand different *directions that would* be conceivable—he knows definitely what particular direction he will now have to investigate.

And beyond that still is the fact that the actions of a great number *of drugs, of* course, are at present known If, therefore, the investigation, the investigator is told, or determines by *himself*, that a mixture or preparation contains this or that drug, it will very much simplify his examination, because he will not have to repeat the things which the long history *of medical knowledge* have already determined

In other words, what might take many years, if he knew nothing about the preparation, he could determine in a relatively short time, if he knew primarily what was in it Still more, of course, if he knew exactly what was in it

ACTIVITY OF A HYPOTHETIC PREPARATION

Q—Now, Doctor, assume it to be the fact that the following substances are absent chemically in the preparation known as Wine of Cardui, namely alkaloids, resins, emetics, saponins and emodin cathartics Would this enable you to form an opinion as to the activity of the preparation? *A*—Yes, it would enable me to form a fairly comprehensive opinion as to the *activity of* such a preparation The classes of substances that you name—you have *named most of them* in classes like alkaloids, etc. These classes of substances that you say are excluded comprise the majority of the known active drugs. It would, therefore, be, as far as all these known *drugs belonging to* these various classes are concerned—the preparation would, as far as these are concerned, be inactive For instance, it would definitely exclude the presence of emetic drugs, the presence of cathartic drugs, and it would also exclude the presence of all, or nearly all drugs that act upon the uterus—or are known to act upon the uterus, such, for instance, as ergot and its principles, hydrastis and its principles, pituitary, adrenalin, and opium—the opium derivatives, metals, cathartics which act upon the uterus *indirectly* I *cannot*, at the moment at least, think of any drug that acts upon the uterus, which would not be excluded by this sort of an examination—any drug that acts definitely upon the uterus, that would *not* be excluded by this sort of an examination

Q—Doctor, what is the average dose of iron in the United States Pharmacopeia? *A*—One grain

Q—Now, assume it to be a fact that Wine of Cardui contains six ten thousandths per cent of iron, have you an opinion as to whether this quantity of iron is of any importance medicinally, when Wine of Cardui is given in tablespoonful doses, three or four times a day? *A*—I have an opinion

Q—What is it, Doctor? *A*—The dose—the proportion of iron which you state there, six ten thousandths of a per cent., would mean that in order to obtain the tonic dose of *iron—one grain*—a quantity of two and one half gallons of the preparation would have to be consumed, or, putting it another way, it would *mean* that in a tablespoonful of this preparation, there would be less than 1/600 of one grain, less than 1/600 of the tonic dose of iron Evidently such a small proportion of iron would have absolutely no significance whatever

Q—Doctor, do you know the *ordinary* dose of volatile *oils*? *A*—Three drops

Q—Assume that Wine of Cardui contains four thousandths per cent of volatile principles, other than alcohol and water, can you tell the jury how much Wine of Cardui would have to be used in order to obtain the average dose, namely, three drops of the *volatile oils*? *A*—One and a quarter gallons

Q—What fraction of three drops of volatile oil would be in a tablespoonful of Wine of Cardui? *A*—One three hundredths of *three* drops

Q—What amount, Doctor? *A*—One three hundredths *of* three drops

Q—Of three drops? *A*—Approximately

Q—Have you an opinion as to whether the volatile *oil* would be of any importance when Wine of Cardui is taken in *tablespoonful* doses, three or four times a day? *A*—Such a *dose as you* named to be present there would have absolutely no *significance* whatever

Q—Do you know the dose of valerianic acid? *A*—About 7½ grains

Q—That is the average dose *A*—About 7½ grains.

Q—Assume it to be a fact that 1/60 of a grain of valerianate is found in a *tablespoonful* of Wine of Cardui, so that two gallons of Wine of Cardui would be required to obtain the dose of 7½ grains, or so that a tablbespoonful would contain 1/450 *of* 7½ grains, have you an opinion, on this hypothesis, as to whether the valerianate in Wine of Cardui is of any importance, when the solution is taken in tablespoonful doses, three or four times a day? *A*—*It is* evidently of no importance.

Q—Doctor, do you know the characteristic principle of *viburnum* prunifolium? *A*—Viburnum prunifolium contains a bitter principle, sometimes called viburnin It contains resin, some *tannin* and some valerianic acids

Q—*Would the* tannin when taken by the mouth exert any action on the system? *A*—No *not on the system* Large doses *of* tannin act as astringent *locally*, when *it is* applied, draw the tissues together but since it is destroyed before it is absorbed it never reaches the system practically speaking, and therefore has no action upon the system proper

Q—What is a resin, Doctor? *A*—A resin is a substance that is soluble in water — no — withdraw that — a substance that is soluble in alcohol and insoluble in water

Q—Would it be soluble in 20 per cent of alcohol? *A*—No, it would not

Q—Assume that the extractive substances contained in Wine of Cardui are practically completely soluble in water glycerin and syrup does this enable you to form an opinion as to whether Wine of Cardui contains the resins of viburnum? *A*—Yes it would enable me to form an opinion You stated in your question that the substances — the extractives are soluble in water and similar solvents Now since the resins are insoluble in water and similar solvents it is evident that the solution — the Wine of Cardui does not contain the resin of viburnum or anything else.

Q—Now why why is that Doctor? *A*—I just explained, that the resin being insoluble—

Q—Insoluble in water? *A*—In water—and you were stating that the residue dissolved in water and there evidently can be no resin there

Q—And the menstruum being 20 per cent alcohol? *A*—In 20 per cent alcohol the same thing would be practically true

Q—Now Doctor you said that Wine of Cardui would on the assumptions we have made contain no resins from viburnum In your opinion then would Wine of Cardui represent viburnum prunifolium? *A*—No it would not represent it

Q—Assume that a certain synthetic preparation is made according to a certain formula which, for the purpose of this question we will call A Assume that other synthetic preparations are made by other formulas variously modified by varying the proportions by varying the methods of extraction and by omitting certain constituents Assume that these preparations were made and analyzed by several chemists working independently of each other, and compared by them with a simultaneous analysis of another preparation namely Wine of Cardui Assume that these chemists found marked differences in all the preparations except that which we named A' but that the preparation made according to the formula A agreed completely with Wine of Cardui *in the following respects* except for such small differences as exist in different samples of Wine of Cardui itself Assume that the respects in which agreement was found are the following Color taste valerianic odor specific gravity reaction solid residue and ash nitrates and nitrogen reducing sugar reaction of the distillate to acids and alkalies and the presence of a bitter principle giving the reaction of cnicin Have you an opinion as to whether the product prepared by formula A is or is not identical with Wine of Cardui? *A*—I have an opinion On the basis of what you said I am prepared to assert that the formula A—preparation made by formula A—is identical with Wine of Cardui

Q—Do you state this Doctor now as a fact? *A*—That I state as a fact

DIFFERENCE BETWEEN CARDUUS BENEDICTUS AND CARDUUS MARIANUS

Q—Are you acquainted with the drugs called carduus benedictus and carduus marianus? *A*—Yes

Q—Are they identical? *A*—No *they are not identical*

Q—What are the differences between them? *A*—The two drugs sometimes called carduus benedictus and carduus marianus—there are other names for them also—are derived from different species of thistles Those different species of thistle differ amongst themselves like the various species of grain differ amongst themselves and one might for the sake of comparison say that the benedictus is something like the wheat and the marianus is something like the oats That however is not the extent — full extent of the difference between these two drugs

In the case of carduus benedictus the entire herb is used the thistle just as it stands is cut off the ground and is used in that way generally while it is in flower In the case of the marianus that is not done but the seeds are collected So that the two drugs bear about the same relation to each other as oat meal would to wheat straw That I should say about expresses the differences between the two drugs

Q—Now Doctor are the constituents of these two drugs identical? *A*—No they are not identical

Q—Why? *A*—The characteristic principle of cnicus benedictus the principle to which the action or any action that it may possess—*or is said to possess—is attributed* is a neutral bitter substance that is called cnicin The benedictus contains practically no fatty oil and substances of that kind

On the other hand the carduus marianus which is prepared from a seed contains like most seeds a great deal of fatty oil It is sometimes used as a source of fatty oil like sunflower or corn oil That is its most abundant constituent. It is not definitely known to contain any cnicin If it does it must be a mere trace the merest possible trace.

One can tell the difference at once if one makes a tincture—an extract of the two drugs One only has to look at them and taste them to realize that the constituents are entirely different. You take an alcoholic extract for instance made from carduus benedictus and it forms a straw colored or a little darker brown solution of very bitter taste It looks a little like Wine of Cardui

You make an extract of the carduus marianus with alcohol and you get an almost clear—almost colorless but somewhat milky fluid. If you taste the two, you get a very marked bitter taste in the carduus benedictus due to that principle that I said is called cnicin If you taste the carduus marianus extract, you get the flat oily taste practically without any trace of bitterness making the two of the same strength, say ten parts of the drug in each case, and 100 parts *of alcohol* or something like that

Q—Then this cnicin which you have been talking about, and which comes from the carduus benedictus, is the bitter principle the neutral bitter principle you have been speaking of? *A*—That is the neutral bitter *principle* that I have mentioned

Q—Now is that, or is it not, the active constituent if it has any active constituent, of carduus benedictus? *A*—It is considered the active constituent, in so far as there is any active constituent present I think *one may say* it is the active constituent

Q—Doctor, can you give us any idea of how much cnicin there is in 30 grains of carduus benedictus? *A*—I think there would be about one fifteenth of a grain

Q—Is it soluble in water? *A*—Fairly so not freely soluble but fairly soluble

Q—Do you know whether the so-called solid extract of viburnum prunifolium and carduus benedictus are used in medicines? *A*—Both of these are used in medicines That is they are official in various pharmacopeias and that means of course that they are medicinal used in medicines

Q—How are they prepared, Doctor? *A*—They are prepared by evaporating either the fluidextract or the decoctions of those drugs The exact process varies in different countries

Q—Well now in this evaporation is heat applied? *A*—That is the way in which they are evaporated

Q—Well does or does not the heat that is so applied injure the drug? *A*—Apparently not

Q—Can these extractives be prescribed in the form of—

Mr Hough—Pardon me Did he say apparently not?

The Witness—Yes

Mr Scofield—He said apparently not

Q—Can these extracts be prescribed in the form of pills capsules and tablets? *A*—Those are the forms in which they are commonly prescribed

Q—Doctor do you know whether viburnum prunifolium and carduus benedictus are ever used in the form of teas? *A*—They are commonly used that way

Q—Assume that the residue of the evaporation of Wine of Cardui is soluble in glycerin and in syrup would there be any—

Mr Hough—In what?

Mr T J Scofield—Glycerin and syrup

Q—Would there be any disadvantage in administering them in this form instead of in 20 per cent. alcohol? *A*—There would be no disadvantage

A—Assume that the residue from a tablespoonful of Wine of Cardui could be perfectly dissolved in two teaspoons of 20 per cent alcohol therefore containing one half the quantity of alcohol to the dose Would there be any disadvantage in administering it in that way? *A*—No—if it can be dissolved in that—as you said—there would be no disadvantage in administering it in that way And if as you said it is soluble in water it could be dissolved in a teaspoonful of 20 per cent alcohol making the dose of one fourth

Q—Making the dose of Wine of Cardui one fourth of a tablespoon? *A*—Yes and the amount of alcohol one fourth

Q—Or one fourth of alcohol? *A*—Yes

Q—And still obtain the action of the drug if the drug has an action? *A*—Fully—just the same.

Q—Just the same as in the tablespoonful dose? *A*—Just the same

Q—Now Doctor you stated that a second method of investigating preparations such as Wine of Cardui is by animal experimentation

Whereupon an adjournment was taken until 2 00 o clock p m of the same day

(*To be continued*)

Machinery of Metabolism.—Carl Voit to whom more than any one else the world owes its fundamental knowledge of nutrition, was accustomed to say in his lectures Continual decompositions of matter are always going on in the living cells and the energy liberated in these decompositions is the power upon which the motions of life depend Phenomena of life are phenomena of motion' In truly poetical language, Rubner the most eminent of Voit's pupils has written, 'Mute and still by night and by day, labor goes on in the workshops of life Here an animal grows, there a plant, and the wonder of it all is not the less in the smallest being than in the largest" The workshops of life require fuel to maintain them and a necessary function of nutrition is to furnish fuel to the organism that the *motions of life continue* Furthermore, the workshops of life are in a constant state of partial breaking down and materials must be furnished to repair the wornout parts In the fuel factor and the repair factor lie the essence of the science of nutrition These two factors operate to bring about death from starvation, either the body s own store of fuel becomes exhausted or a part of the machinery necessary for life wears out—Graham Lusk The Fundamental Basis of Nutrition

Correspondence

A Report on the Efficiency and Nontoxicity of Arsenobenzol

In The Journal, March 18, 1916, p 867, Ormsby and Mitchell of Chicago reported on the comparison between salvarsan and arsenobenzol I was one of the first who through Dr Schamberg's kindness was able to give this drug an extensive trial, and according to his statement have at the present time had perhaps the largest experience with it Inasmuch as the Philadelphia product is about to be issued to the medical profession at large, it seems proper to supplement the Ormsby-Mitchell report in order to apprise the profession that the remedy may be used with perfect safety The cases reported herein have been studied with two main considerations in view first, the possible toxicity of the new drug, and second, its relative therapeutic value as compared with old salvarsan

During the past six months, 243 cases of syphilis have been treated at the University Hospital with arsenobenzol These patients have received in all 612 injections The accompanying table classifies the types of cases treated

TYPES OF CASES TREATED

Type	No
Cases of primary and secondary syphilis	98
Cases of gummous syphilis	18
Cases of latent syphilis	85
Cases of hereditary syphilis	14
Cases of tabes dorsalis	14
Cases of acute cerebrospinal syphilis	11
Cases of general paresis	3

In addition, I have given about sixty intraspinal injections, using the arsenobenzol in a dosage of from 0 00033 + to 0 0005 gm Patients thus treated were for the most part tabetics and persons with cerebrospinal syphilis

With regard to the efficiency of the drug, it was noted that the immediate lesions disappeared as promptly as though they had been treated with the older salvarsan preparation In 116 cases in which there were manifest cutaneous syphilids, there have been but four recurrences One of these was a malignant pustular syphilid which returned after three injections in four months with a large gumma of the forearm The other three were in the nature of neurorecidives At the outset, in order to test out the product, and not being familiar with its properties, I gave the drug in somewhat smaller doses than is my custom with the older preparation Thus whereas I customarily give 0 3 mg as an initial dose at the outset, I gave but 0 2 mg, and the succeeding doses were correspondingly smaller I am inclined to regard the four cases of recurrence, therefore, as due to underdosage, and it is noteworthy in this connection that the four cases occurred among the first ones which I treated At the present writing I am using the arsenobenzol in repeated doses equivalent to the dosage employed in the use of old salvarsan In the 612 injections given we can attest to the fact that only three cases showed any reaction These were in the nature of allergic reactions, dyspnea, slight cyanosis and slight cardiac depression occurring during the third injection In a few other cases in which many lesions were present, a rather sharp Herxheimer reaction occurred, as of course happens with the older preparation as well

The intraspinal treatments have all been well borne, have been unattended by any untoward accident, and the therapeutic results have been identical with those produced by similar injections of old salvarsan The method employed has been a modification of the Ogilvie method, namely, the introduction of the salvarsan solution directly into the spinal fluid

From my experience with arsenobenzol it may be concluded that

1 The immediate therapeutic results are fully as good as those following the use of old salvarsan

2 Given with the proper precautions, the drug has shown itself fully as little toxic as the older preparation

These two conclusions refer to intraspinal medication as well as to intravenous

Bothriocephalus Latus Infection

To the Editor —In The Journal, May 20, 1916, p 1618, Dr J J Singer reported a case of *Bothriocephalus latus* infection In view of the comparatively few cases that have occurred in this country, or at any rate have been reported, it might be well to place on record one of which the specimen is in the Army Medical Museum The specimen was received Feb 4, 1864, from Dr Hennell Stevens, U S Army, then Medical Storekeeper at Memphis, Tenn Unfortunately he failed to furnish a history, and none has ever been received The specimen is in several pieces, in all about 80 feet Its character as *Bothriocephalus latus* was recognized at once

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed Every letter must contain the writer's name and address, but these will be omitted, on request.

SOME CHAUCERIAN MEDICINE

To the Editor —1 Can you give me any historical essay references based on the middle English literature, especially Chaucer's lines on the doctor in "Canterbury Tales"?

2 What is the significance of (*a*) "gold potable" and (*b*) "image making" in those lines? C C Hinton, M D, *Atlanta, Ga*

Answer —1 Norman Moore's Fitzpatrick Lectures for 1905-1906, entitled "Medicine in the British Isles," Oxford University Press, and Walsh's "Old Time Makers of Medicine," Fordham University Press, may be referred to A good edition of Chaucer for this study is that of W W Skeat, in the notes to which practically all the information requested is found

2 (*a*) "Gold potable" The reference is probably to "Les remonstrances de nature," by Jean de Meun

> C'est le fin et bon or potable
> L'humide radical notable
> C'est souverain medecine

Throughout the middle ages and even much later it was supposed that aurum potabile was a sovereign remedy It is referred to in "Humour Out of Breath," Act 1, Scene 1, in a footnote which calls it "the universal medicine of the alchemist prepared from gold, mercury, etc The full receipt will be found in the fifth and last part of the 'Last Testament of Friar Basilius Valentin,' London, 1670" See also Thompson's "History of Chemistry," i, 164, and Burton's "Anatomy of Melancholy," Part 2, Section 4

(*b*) "Image Making" The reference here is to the belief that by making images of persons from properly chosen materials and *at the right time*, effects, favorable or unfavorable, could be produced on the originals The ascendant is the point of the zodiac which is rising from the horizon at any given moment, and serves as the means of fixing an astrologic epoch The whole meaning of the passage, therefore, is that the doctor knew well how to choose a fortunate moment for making images to be used as charms to help his patients

USE OF ANIMAL GELATIN

To the Editor —1 What is the value of animal gelatin as a food?

2 *In case it is desired to use gelatin, are commercial preparations such as "jello" sufficiently pure gelatin to be used? If not how is it best used* W R Smith, M D, *El Paso, Tex*

Answer —1 Gelatin is an artificial derivative of collagen, the essential basis of white fibrous connective tissue or bone It is a readily digestible protein substance, long classed as an "albuminoid," and known to be inadequate as the sole source of protein in the dietary Gelatin contains approximately the same amount of nitrogen as the more typical proteins, and yields most of the amino acids characteristic of this group of nutrients, but it does not contain the tyrosin cystin or tryptophan groups, all of which are now believed to be indispensable nitrogenous nutrient units for the body For this reason when gelatin alone is supplied as the nitrogenous portion of the ration, nutritive failure ensues

Although gelatin alone cannot maintain nitrogenous equilibrium in nutrition, it can replace a considerable part of the protein usually present in the diet without detriment to the organism It can restore the nitrogenous waste of the body to a certain extent, and yields energy as other foodstuffs do Gelatin attracts attention as a food because of the readiness with which it is digested and tolerated, its freedom from some of the more objectionable products of putrefaction such as indol (owing to the lack of the antecedent tryptophan group), and because of the culinary advantages that it possesses When used liberally in the diet, gelatin should be furnished along with other more complete proteins, such as those of egg or milk It should be noted that gelatin, like other proteins, may yield sugar in the diabetic Inasmuch as gelatin is almost invariably served in the form of jellies which consist very largely of water (usually to the extent of 95 per cent.) the actual nutrient possibilities of an ordinary serving must not be overestimated An ordinary 2 ounce package of gelatin may suffice for several pints of jelly This bulk is often satisfying to the palate when small intake of nutrient is desired

2 We assume that our correspondent refers to the use of gelatin as food Most of the widely advertised commercial gelatin products are sufficiently pure to serve acceptably in the dietary Flavors form an occasional adjuvant There need be no difficulty in selecting a proper food specimen from among the various brands at present sold as gelatin by American makers Brands bearing special trade names are usually considerably higher in price per unit of nutrient They sometimes include flavoring or coloring products in separate packages in the containers According to published analyses, some of the preparations of jelly powders, such as the one mentioned by our correspondent, widely used as quick desserts, consist chiefly of sucrose with sufficient gelatin to make a jelly, and are variously flavored and colored to simulate the color and flavor of natural fruits As a rule their compound nature is more or less clearly indicated on the label Analyses of gelatin preparations and jelly powders will be found in the reports of the Connecticut Agricultural Experiment Station, Food and Drug Products, for 1909 and 1913

Preparations of so-called "vegetable gelatin" usually consist of agar-agar or the gelatinizing carbohydrates of Irish moss (*Chondrus crispus*) and are essentially without nutritive value, though they form attractive dishes and may serve as a vehicle for other nutrients or for laxative purposes

PRACTICE IN GOVERNMENT LANDS

To the Editor —Please give me information concerning the practice of medicine on government property, national parks Indian reservations etc.

R. B Denver

Answer.—The U S Department of the Interior has just issued a bulletin covering the above It states that no business for profit can be conducted on government lands without special permission from the department. That medical service may be available for tourists and others, however, physicians are granted permits by the department to practice in several of the national parks A nominal fee is exacted for these permits, which are granted only to those who are licensed under the laws of the state in which the park is located This relates chiefly to the Yellowstone National Park in Wyoming

At the Hot Springs reservation, Arkansas, physicians who desire to prescribe the waters must register in the office of the supervisor This requires the passing of a medical examination prescribed by the secretary of the interior No fee is exacted for registration, but the applicant must be a physician registered under the laws of the state of Arkansas

In the various Indian reservations contract physicians and full time physicians are utilized Contract physicians are employed after bids have been obtained from reputable licensed physicians practicing in the vicinity where any vacancy occurs Employment follows only after approval has been granted by the Civil Service Commission Full time physicians are employed only after certification from the Civil Service Commission, which from time to time conducts examinations of physicians for the Indian Service.

MEDICAL COLLEGE MERGER IN PHILADELPHIA

Three medical colleges in Philadelphia have just been merged into one larger teaching institution which now provides for both undergraduate and graduate medical instruction The union of the Medico-Chirurgical College of Philadelphia with the University of Pennsylvania as its Graduate School of Medicine has been under advisement for several months and later efforts were made to bring Jefferson Medical College also into the merger These efforts have been successful

On Friday, June 2, a plan for the merger of the Jefferson Medical College with the University of Pennsylvania, School of Medicine, was submitted by a joint committee to the board of trustees of the two institutions and was unanimously adopted by those boards The joint committee consisted of Provost Edgar F Smith, Effingham B Morris and Randal Morgan, representing the University of Pennsylvania, and President William Potter, Simon Gratz and Alba B Johnson representing Jefferson Medical College. The plan as adopted is as follows

The Plan

The boards of trustees of the University of Pennsylvania and of Jefferson Medical College of Philadelphia have agreed that the facilities now possessed by them for instruction in medicine and surgery shall hereafter be utilized and enlarged in combination rather than in a continued distinctiveness

The identity of the two institutions, with maintenance of the inherited values of their respective names, and without change in the rights, powers and authorities vested in them by their respective charters and organic laws, is hereby recognized and preserved inviolate

The following plan is suggested for the accomplishment of these purposes

First—The united medical schools hereby established shall be named and known hereafter as "The Medical School of the University of Pennsylvania and the Jefferson Medical College of Philadelphia"

Second—The respective faculties of the two schools shall hereafter become one faculty for purposes of instruction to students, divided into groups of individual members from both, e g, surgical group, medical group, anatomy group, physiologic chemistry group, research group, etc Each group shall meet together annually and decide on a roster determining and providing what each individual professor shall teach, where he will teach, and the hours of his instruction Students may then elect which professor or professors in given subjects they will hear throughout the term

Third—The government of the united medical schools in its general administration and in its business affairs shall be vested by action of the boards of trustees of the two institutions in a joint committee of eight to be known as the "United Medical Committee," of which the provost of the University of Pennsylvania shall ex officio be chairman, and the president of the Jefferson Medical College of Philadelphia shall be vice chairman, and the other six members shall be three trustees from each board—not of the medical profession—appointed by each of the boards of the two institutions and serving during the pleasure of the respective boards

Fourth—The supervision of academic work, of hospital work, and of research work shall be vested in a dean and a vice dean who shall discharge the usual duties incident to these positions, with jurisdiction over both of the present schools and of such others as may be established They shall be elected annually by the United Medical Committee on the nomination of the chairman and vice chairman of that committee, each of the united medical schools being represented in such election

Fifth—The dean and vice dean shall constitute a curriculum committee, which shall be charged with the duty of making a roster that will properly divide the hours of instruction among the different groups and obviate any difficulties that may arise in the selection of hours

Sixth—Examination in course and for final degrees shall be conducted by a commission selected and agreed on from year to year by the dean and vice dean in consultation with the several groups

Seventh—Elections of members of the faculty of the school, or appointment of any person on the teaching staff, shall be made by the United Medical Committee, subject to confirmation of such elections or appointments by the respective boards of trustees of the two institutions, and subject to and in accordance with the provisions of their respective statutes and by-laws In like manner changes which it may be desirable to make from time to time in the faculty or in the teaching staff, and retirement of all professors, assistant professors, or instructors, shall be made by appropriate action of the respective boards of trustees, in accordance with their respective statutes and by-laws, only on and after recommendation by the United Medical Committee

Eighth—The diplomas of graduates of "The Medical School of the University of Pennsylvania and the Jefferson Medical College of Philadelphia" hereby established shall be signed by the provost of the University of Pennsylvania, the president of the board of trustees of the Jefferson Medical College of Philadelphia, and by the dean and vice dean, and shall bear the corporate seals of both institutions

Ninth—The respective alumni associations of the two institutions may continue their independent existence, and any graduate of the united medical schools may join, at his pleasure, either or both of said associations

Tenth—There shall be a treasurer chosen by the United Medical Committee, and subject to the directions of that committee as to the receipt and expenditures of available resources

Eleventh—The budget of estimated income and expenditures of the united medical schools shall be presented, each year, by the United Medical Committee to the respective boards of trustees, for their consideration and approval, and said committee shall have no authority to expend any moneys, other than those provided by the said budget, without the approval of the respective boards of trustees

Twelfth—No moneys or real or personal property heretofore given, devised or bequeathed, or that may hereafter be given, devised or bequeathed to either of said institutions separately, for a specific purpose, shall be in any manner diverted from such purpose

Subject to this provision, all tuition fees, income from invested funds, gifts by individuals, legislative appropriations, or receipts from any other source, shall be applied to the support of the united medical schools

Thirteenth—All moneys, or property of any description whatever, whether real or personal, now constituting the endowment fund of either of the hospitals connected with the two institutions, and all gifts, devises, bequests, or appropriations by the Commonwealth of Pennsylvania that may hereafter be made to either of them specifically, shall continue to be the separate property of such hospital, but wherever any such gift, devise, bequest or appropriation shall hereafter be made to said hospitals jointly, or as constituent parts of the united medical schools hereby established, a division shall be made between the two hospitals in accordance with their needs, by action of the United Medical Committee, and such division shall be set forth in the annual budget

Fourteenth—Except so far as they shall be used for clinical purposes and the instruction of students of the united medical schools, the respective hospitals of the two institutions shall continue to be under the charge and control of their respective boards The use of these hospitals for clinical and teaching purposes shall be under the direction of the United Medical Committee, pursuant to such arrangements for such use as shall have been made by that committee with the respective boards of trustees

Fifteenth—The students of the united medical schools shall have the use of the libraries and museums of both schools They shall also have the use of the university's dormitories, and all other privileges and relationships now enjoyed by the students of all other schools and departments of the university, or which may be hereafter enjoyed by them, and on the same terms and conditions

The Institutional Care of the Insane in the United States and Canada By Henry M Hurd, William F Drewry, Richard Dewey, Charles Pilgrim, G Alder Blumer and T J W Burgess Edited by Henry M Hurd, M D, LL D, Emeritus Professor of Psychiatry, the Johns Hopkins University Cloth Volume I Price, $2 50 Pp 497, with illustrations Baltimore The Johns Hopkins Press, *1916*

This series, of which only Volume I has been issued, will concern modifications of methods for the care of the insane in America It is evident that during the past half century a gradual evolution has occurred in the care of the insane which points toward the ultimate cure of such persons The authors state in the preface

> The movement towards the prompt treatment of curable cases without the formality of legal commitment, and under the same conditions as in admission to a hospital for general bodily disease, gives every hope that at an early day cases of recent attack may be received everywhere promptly, and that greatly increased numbers can be cured Cases of a chronic nature are also now much more satisfactorily dealt with in institutions on the cottage plan, with outlying colonies for the employment of patients, and have a correspondingly better opportunity to attain self support These movements promise to make material changes in future methods of caring for the insane

Volume I takes up the history of the Association of Superintendents of American Institutions for the Insane which existed from 1844 to 1893, and the American Medico Psychological Association which followed The book considers the care of the insane from the early colonial days down to a more modern period A special chapter is given to the work of Dorothea Lynde Dix, then follow the growth of the country system and colonies, and a discussion of the growth of hospitals and development of hospital architecture Chapter VI is devoted to reforms in caring for the insane, medical and nonmedical treatment employment, individual treatment, and the growth of psychopathic hospitals and research work in hospitals The next chapter considers the establishment of training schools for nurses and training schools for attendants, following which is a short chapter devoted to the private care of the insane Then follows a chapter on the law of insanity the commitment and discharge of the insane, admission of voluntary patients and the care of the criminal insane Immigration and the care of the alien-born in relation to the state cost of insanity are the exceedingly important topics next considered Another chapter is devoted to insanity among the negroes, North American Indians and those in South Dakota, the Chinese and Japanese in the United States The last two chapters of this volume are devoted to a census of the insane, giving statistics of the population in various states, the final one is devoted to insanity in Canada

The work is thorough, interesting and practical, a credit to all who have been concerned in its compilation

HYSTERIA AND ACCIDENT COMPENSATIO Nature of Hysteria and the Lesson of the Post Litigation Results By Francis X Dercum M D Ph D Professor of Nervous and Mental Diseases Jefferson Medical College, Philadelphia Cloth Price, $2 Pp 120 Philadelphia The George T Bisel Company 1916

This book presents the subject of "accident hysteria," in as condensed and readable a form as possible, for legislators, lawyers and sociologists 'Railway spine" came with the advent of the railroad and has frequently appeared in personal injury litigation According to the author after an accident there often develop cases of "traumatic hysteria" or, as the author tersely puts it, "litigation hysteria" This is a condition which preexists in the individual It is not the same as hysteria caused by a bona fide injury or fright It is produced by the psychology of compensation The author s experience has shown that these imaginary ills take flight with the settlement of the case The same situation is to be found under the workmen s compensation acts Usually these laws have made no adequate provision for separating the spurious from the real A detailed examination of the patient made by an impartial scientific specialist will usually distinguish between the two In Germany by reason of intensive industrial legislation, this so-called "pension hysteria" has developed to a greater extent perhaps, than in many other countries This seems to be by reason of the German method of paying compensation, which continues during the period of disability while other countries have a cash settlement basis Thus, in Denmark the percentage recovering from traumatic neuroses is 93 6 In Germany it is only 9.3 per cent The author concludes that the solution of the problem is to deny compensation in cases of "litigation hysteria ' This has been advocated in both Germany and France, in Sweden this method is actually pursued by the insurance societies To bring legislator lawyer and judge to a proper understanding of these cases in order that justice under the law may more nearly obtain is the work of the scientific expert. In the opinion of the author, this is a matter of education and an immediate and concerted effort should be made by the medical profession to bring about its consummation

A LABORATORY COURSE IN SERUM STUDY Bacteriology 208 Being a Series of Experiments and Diagnostic Tests in Immunology Carried Out in an Optional Course Given to Medical and Graduate Students in the Department of Bacteriology, College of Physicians and Surgeons Columbia University New York by the Writers By Hans Zinsser M D J G Hopkins, M D and Reuben Ottenberg M.D Cloth Price, $1.25 Pp 184 New York The Macmillan Company 1916

The primary purpose of this book is indicated by the title, and seems to be to guide the student carefully in carrying out fundamental experiments, and to draw the conclusions indicated by the results The book will be of much service to those planning similar courses and to students and physicians who wish to become familiar with the technic of immunology and serology, not merely for the purpose of conducting diagnostic tests, but also in order to grasp the fundamental principles

Medicolegal

Responsibility for Loss of Drainage Tube in Body of Child

(Cyr vs Landry (Maine), 95 Atl R 883)

The Supreme Judicial Court of Maine sustains a motion by the defendant for a new *trial after a verdict against him* for alleged malpractice in connection with the loss of a drainage tube in the body of a child The court says that the only issue under the plaintiff's declaration was whether the tube was lost through the negligence of the defendant, but the case was tried also on the issue of whether if the tube had entered the pleural cavity through accident, or the fault of another than the defendant, did the defendant then exercise such care to discover whether it was in the cavity as ordinary skill and knowledge required? In other words was he negligent, in view of the professional skill required in not making a reasonable effort to discover whether the tube was in the cavity? Another surgeon had operated on the child October 16, for the removal of fluid from the pleural cavity and last saw the patient on the 31st The plaintiff took charge of the case, November 2 If the drainage tube which the other surgeon left fastened with a safety pin through the gauze and the tube was in the body of the child when the defendant came, he was not guilty of malpractice If he took the tube out and attempted to secure it by the mere use of sticking plasters and on that account it dropped into the cavity, he was guilty The testimony in the case was conflicting but the mere fact of conflicting testimony is not a sufficient basis, in all cases for the foundation of a verdict The evidence was ample to persuade a reasonable *mind* that the tube was lost through the improper manipulation of the dressing by the child's mother, and that the latter knew or had every reason to know, that through her own fault it had dropped into the cavity And in view of the fact that it was impossible for the tube to enter the cavity unless the safety pin was removed, and that the defendant was completely misled by the denial of the child's mother that she had interfered with the dressing, and that she was charged with every reason to believe that the tube was in the body yet withheld the information it is the opinion of the court that when the defendant directed her time and again to take the child to the hospital for an operation, if she believed the tube was *in the body*, he exercised such care under the circumstances of the case, as ordinary medical skill and knowledge required The verdict rendered against the defendant should be set aside on both issues

Adulteration and Misbranding Due to Alcohol—Scope of Pure Food Law

(Hoefler vs Mickle (Ore), 153 Pac R 417)

The Supreme Court of Oregon affirms a judgment in favor of the defendant, whom it was sought as food and dairy commissioner of the state, to prevent from seizing and confiscating some candy manufactured by the plaintiff *and styled* "Centennial Chocolates" which contained not to exceed 1 05 *per cent by volume of alcohol without* its being mentioned in the label The court says that this litigation arose under the pure food law of Feb 26 1915 The questions to be determined were whether the plaintiff had in possession with intent to sell or distribute an adulterated article of food or one which was misbranded The object of the act *is* to promote purity of food products and to protect the public against deception in such articles To this end the law has denounced adulterations and deceptive labels In such cases as the one in hand, for instance, a parent buying candy for his children has a right to know whether it is indeed pure confectionery or a mixture of sugar and whisky or other intoxicating liquor Chocolate, a product of cacao seeds roasted and ground and often mixed with sugar, is a harmless article of food and *if true to the label* admitted in this suit, would not be harmful to any one On the other hand if it contains an ingredient "injurious or detrimental to health of consumers,' as mentioned in Subdivision 16 of

Section 21 of the act, or, as stated in Subdivision 5 of Section 35 on misbranding, if it contains "any deleterious substance", it is misbranded within the meaning of the act Alcohol is classified by all toxicologists as a poison Considered in the light of legislation from the foundation of the state to the present, it is a substance deleterious to health It has always been under the ban of the law as an enemy to the physical welfare of the people Without reference to whether or not a food commissioner has established a standard of purity for the article of food called "candy," the fact that the confection in question contained 1 05 per cent of alcohol was sufficient to bring it within the sixteenth subdivision of Section 21 defining an adulterated article of food, for the simple reason that free alcohol is injurious and harmful to the health of any one who partakes of it It was strongly urged that Section 35 of the act is indefinite and uncertain, and particularly that it is impossible to determine whether the third subdivision relates to drugs or to food By its own terms the section is made to apply to all articles of food Referring to the earlier Section 20, it is found that the term includes all articles used for food or drink or intended to be eaten or drunk by man, whether simple, mixed or compound This definition is wide enough to include within its terms drugs which are intended to be taken inwardly by individuals In the statutory sense, therefore, such drugs are food, and for the purposes of Section 35, construed with Section 20, it matters not whether Subdivision 3, stating certain cases which shall be deemed misbranding, be applied to the bread of the baker, the candy of the confectioner, or the drugs of the physician The stipulation of facts measured by this enactment disclosed that the article in question was not only adulterated, but also misbranded

Violation of Medical Practice Act Sufficiently Alleged

(Young vs State (Tex), 181 S W R 472)

The Court of Criminal Appeals of Texas affirms a judgment of conviction of defendant Young of unlawfully practicing medicine The court says that the defendant moved to quash the information and complaint because they did not allege that he had not recorded a certificate or diploma in the county of his residence They alleged that he practiced medicine "without having first obtained from an authorized board of medical examiners a certificate of professional qualifications, and without having a diploma from some accredited medical college" If he had obtained a certificate or diploma and failed to record it in the county of his residence, he would be guilty, and if he had such certificate or diploma, it would be necessary to allege that he had not recorded it in the county of his residence before a conviction would be authorized But when the information alleged that he had never obtained a certificate or diploma, this language necessarily implied and charged that he had not recorded authority in the county of his residence It is always better to follow the language of the statute, but this is not absolutely essential, if language of equivalent import is used Nor did the court err in striking out a plea of former jeopardy or acquittal This information alleged that on or about March 12, 1915, and thence continuously up to the date of filing the complaint in this cause, which was April 27, the defendant did unlawfully engage in the practice of medicine, and did prescribe for and visit Mrs Thad Pines, etc This covered a specific time from March 12 to April 27 The other information also covered a specific time, from May 10, 1915, to May 12, 1915, and alleged that the defendant engaged in the practice of medicine, and did treat one W W Prior They were separate and distinct offenses alleged, and occurred at separate and distinct times The state had to prove in one instance that the defendant treated and offered to treat Mrs Pines, and in the other Mr Prior As the statute specifically defines the words "practicing medicine," the court did not err in not admitting testimony as to the general meaning of those words Furthermore, there was no error in admitting the testimony of one Braden, which showed that the defendant treated his wife and that he received his board and lodging as compensation for the medicine furnished and services rendered

Thirty First Annual Meeting, held at Washington, D C, May 9 11, 1916

Dr Henry Sewall, Denver, in the Chair

SYMPOSIUM ON ACIDOSIS

Biochemistry of Acidosis

Dr Lawrence J Henderson, Boston The equilibrium between acids and bases is essential to life Fluctuations in equilibrium occur, but normally the limits of fluctuation are narrow Wider fluctuations in these equilibriums occur pathologically, but the acid-basic fluctuations do not, as a rule, involve changes in the H-ion concentration Acidosis is defined as any disturbance of the acid basic equilibrium whereby the power to resist acids in the body is lost It is now possible to say that the main change in acidosis is the loss of blood bicarbonates The bicarbonates are to be regarded as the *third* constituent of the blood reckoning water first, salt second, and bicarbonate third This third constituent is specially subject to fluctuations, owing to the constant physiochemical interchanges between blood and respired air Since H-ion concentration is proportional to the reactions between bicarbonates and free carbon dioxid, the ratio of free carbon dioxid and bicarbonates is kept fairly constant by the mechanism of ventilation Hence, H-ion concentration is now regarded as the hormone of respiration The maintenance of the acid-base equilibrium becomes more complicated in pathologic states, and always is related to and dependent on the general metabolism of the body Beneath all metabolism is a constant diminution of blood bicarbonates, unless repaired, this leads to acidosis The carbon dioxid tension of alveolar air and of the blood, together with the measure of alkali ingestion, are the measures of acidosis Neither ammonia concentration nor urinary findings are safe guides Attempts to explain general pathologic states on basis of H-ion concentration or acidosis are not justified Any attempt to treat a disease like nephritis by the indiscriminate administration of large amounts of alkali is malpractice Small amounts of alkali, given over a long time, are allowable, and when they are so given, acidosis is impossible

Acidosis in Infants and Children

Dr John Howland, Baltimore Acidosis in children is a dangerous but often an acute, self-limited disease It is not merely an acetonuria, but depends on a loss of the acid base equilibrium of the blood Hyperpnea is the clinical sign laboratory tests are the indexes, these being carbon dioxid tension of alveolar air, H-ion concentration of blood, and alkali reserve of blood The natural low level of carbon dioxid tension and low H-ion concentration in the young explain susceptibility to acidosis Onset of acidosis is marked by hyperpnea, coma soon ensues the alkali reserve may be restored, but unless done quickly, death follows The presence of acid phosphates in the blood in excess (from five to fifteen times the normal), continued long enough, would rob the body of bases Restoration of bases does not always stop the accumulation of acid phosphates Acidosis is seen in many diseases of infancy and childhood, and should always be kept in mind, its early, rational treatment may be the means of saving life

Acidosis in Diabetes

Dr R T Woodyatt, Chicago The explanation of the occurrence of acidosis in diabetics depends on definition of difference between the diabetic and the normal individual The proportionality between glucose utilization and wastage depends on rate of intake. It may be said that with a rate of glucose intake high enough, the normal individual becomes diabetic, with the intake low enough, the diabetic acts like the normal individual The difference is in the wastage The occurrence of acidosis in diabetics depends on this It has been found that one molecule of carbohydrate must be burned to care for three molecules of higher fatty acids If this ratio cannot be maintained, the body "smokes" with unburnt fats, and acetone betahydroxybutyric acid, and diacetic acid appear in the urine In diabetics the absolute rate of carbohydrate utilization is low, and it is necessary to bend down the rates of protein and fat metabolism to meet that of the carbohydrates Thus the application of rest, warmth and fasting in the treatment of diabetes is rational Acidosis in diabetes may always be accounted for in the way described, except in certain cases, as its occurrence in the course of septic processes, such cases may be called accidental rather than diabetic acidosis

Acidosis in Acute and Chronic Diseases

Dr. Channing Frothingham, Jr., Boston The finding of acidosis in other diseased states than diabetes led to a study of carbon dioxid tension of alveolar air, H-ion concentration of blood, acetone and ammonia-nitrogen output in urine, and soda utilization in a large and diversified series of cases The results of the study may be summarized thus In adults, acidosis of the diabetic type does not exist in a large number of miscellaneous diseases, but a certain form of acidosis does exist (as shown by Howland) which may be recognized by available tests

Investigations in Diagnosis and Treatment of Acidosis

Dr. Leonard G Rowntree, Minneapolis The H-ion concentration of the blood must be kept at a normal level to maintain life Studies with the electrometric method have established the fact that the dialysis-indicator method may be depended on The method is simple and absolute Studies of the "buffer" values of the blood (ability to care for acid-basic fluctuations without disturbance of the H-ion concentration) indicate the normal to be 0 36 In acidosis, the "buffer" value for both acids and bases is reduced or lost The mechanism of changes in 'buffer' value is not known It may be said that true acidosis occurs when there is a change in H-ion concentration of the blood, compensated acidosis occurs when there is a change in the buffer value without change in H-ion concentration In disease states, acidosis and disturbances of H-ion concentration may be corrected without benefit to the patient The administration of alkalies beyond the point of correction of acidosis is harmful alkali therapy, therefore, should be controlled by available tests

Discussion on Symposium on Acidosis

Dr Yandell Henderson, New Haven, Conn The acidosis we used to talk about is certainly not the acidosis of today The acidosis of diabetes is not the acidosis of asphyxia, or of nephritis We might better in one case speak of ketonuria, and in another, of low carbon dioxid states, and so on In 1911 I was a member of Haldane's Pike s Peak expedition, and all of the party had acidosis when a sufficient altitude was reached, if the carbon dioxid tension is taken as the index I am rather skeptical of the hurtful effects of acidosis I have not seen figures indicating a more severe acidosis than I persistently had on Pike s Peak when I was feeling particularly well The description given by Dr Henderson was on the basis of sea level data But on going above sea level one s acidosis increases with the altitude, in a caisson, acidosis diminishes Miss Fitzgerald of the Haldane expedition, has shown this as a result of hundreds of observations made at various altitudes The net result of her work is that one can determine the altitude of any community by the measure of the carbon dioxid tension of the alveolar air of the inhabitants, or, in other words, by their acidosis It is safer to keep in mind the facts From the urinary standpoint, acetonuria may be found, from the respiratory standpoint, variations in carbon dioxid tension or volume of ventilation may be measured, from the point of view of the blood, disturbances of H-ion concentration may be noted, and other measures of the body's alkali-acid balance may be made But if all of these measures are to be accepted as measures of acidosis, we shall encounter cases of acidosis in which the acidosis is not a condition of acid blood at all, because the H-ion concentration of the blood may still be normal It is necessary, therefore, to formulate and keep clearly in mind just what in the future shall be known as acidosis

Dr E J Van Slyke, New York Much of the discussion has dealt with the relations between the kidney, lung and blood functions in acidosis The phenomena arising in these various systems are corollaries one to another I agree with Henderson that acidosis is a loss of the normal relationship between acids and the bicarbonates of the blood I also agree with Rowntree's classification of compensated acidosis and true acidosis on the basis of undisturbed and disturbed H-ion concentration, respectively With regard to reduction of carbon dioxid tension of alveolar air, this is only an indirect measure of the H-ion concentration of the blood, and it cannot be regarded as synonymous with acidosis It is an exact measure of the H-ion state of the blood only when the lungs are functioning normally and under fixed conditions of temperature and atmosphere The same may be said of the urinary findings certain urinary changes are recognizable and acceptable as indirect evidences of acidosis, but they are not synonymous with acidosis, and they depend on renal integrity and other factors for constancy

Dr Theodore C Janeway, Baltimore Thus far we have talked of acidosis in terms of ketonuria, but it has now been shown that the modern conception of acidosis, acidosis in its strict sense, is the true cause of diabetic coma Most of the criticisms have been made on the fact that acidosis is merely a biochemical event and not a just measure of disease, but it is the acidosis that causes the hyperpnea, etc and it is possible to conceive of acidosis as the cause of functional disturbances without sacrificing the truth of Henderson's remark about the nonspecificity of the blood changes in this condition The newer types of acidosis have to be recognized it is only necessary to remember that there are fundamental metabolic differences in the origins of the various types

Dr E P Joslin, Boston Two thirds of all diabetics (all diabetic children) die in coma, in fact, all diabetics dying in the first year of the disease die of coma If it can be shown that the number of diabetic fatalities in the first year of the disease has been lessened, this must be because the treatment of acidosis has improved with the improved treatment of diabetes Such statistics are now available and show that the mortality of diabetes in the first year has been greatly reduced

Dr C F Hoover, Cleveland One point bearing on the relation between acidosis and carbon dioxid tension of alveolar air needs to be emphasized There seems to be an impression that there is a definite relationship between carbon dioxid tension of alveolar air and the amplitude of ventilation There is no such definite constant relationship I have seen cases of hyperpnea without acidosis, and cases of acidosis with hypopnea

Dr H A Hare, Philadelphia Thirty years ago I learned in Ludwig's laboratory that the blood is the most carefully protected tissue of the body, and that one should be careful to do no harm by introducing strange substances into it This warning should be heeded in view of what has been said here about the harmful effect of too active alkali therapy in acidosis

Dr. Lawrence J Henderson, New Haven, Conn It is clear that in a great variety of diseases there is a loss of ability to protect the blood against acids, and this condition ought to be called acidosis Because alkalies have been abused is no reason for refusing bicarbonates in small quantities and over long periods, for bicarbonate is the *third* constituent of the blood While acidosis cannot be held to be the cause of disease, it can be held to be the cause of syndromes in disease, for one, he believes that acidosis is the cause of diabetic coma It is possible to overcome the acidosis of diabetic coma without curing the condition, as had been pointed out This may be due to the fact that the cells of the body are not so readily and quickly influenced by substances introduced into the blood in treatment, and evidence of acidosis may disappear from the blood while the condition persists in the tissues

(To be continued)

THE AMERICAN NEUROLOGICAL ASSOCIATION

Forty Second Annual Meeting held at Washington, D C, May 8 10, 1916

The President, Dr Lewellys F Barker, Baltimore, in the Chair

Presidential Address War and the Nervous System

Dr L F Barker, Baltimore So far as wounds of the brain and spinal cord are concerned, the accepted views regarding topical diagnosis are being corroborated It has been established that certain organic lesions of the central nervous system may be caused by modern high explosives without external wound Surgeons are unanimous in urging the thorough investigation of every head wound, no matter how trivial it may at first seem to be As regards the peripheral nerve injuries, it has been shown that loss of power due to section of tendons or muscles may sometimes be confused with paralysis due to lesions of the nerves themselves Contrary to what many expected, nervous states not due to organic lesions, though fairly numerous, have in reality made up but a very small proportion of the total number incapacitated by the war All the well known types of the functional nervous disturbances have been encountered As regards the psychoses, it is surprising that such a small number of cases of insanity have been reported It is asserted that the majority of soldiers in whom psychoses have been observed either had symptoms of the disease before the war or had given definite evidence of predisposition to mental disorder The evidence seems to favor the view that the human nervous system is today better able to stand strain than ever before in its history

The Differentiation and Organization of Sensations

Dr Stewart Paton Princeton, N J As the result of observations on the embryos of some of the higher vertebrates I want to emphasize two points first, the great necessity of looking at the neurologic phenomena from a broad biologic standpoint, and second, the great value that still comes to us from a study of comparative neurology In the chick embryo of from fifty-five to fifty-seven hours of incubation, the motor half of the reflex arc is developed far in advance of the sensory half This tract is developed from the lower caudate quarter of the cord up to the level of the third nerve At 120 hours the development of the third nerve to its terminal distribution can be followed Evidently this is an ancestral inheritance The sensory half of the arc is very gradually superimposed on the motor sector When the embryo first responds to stimuli from the outside world the first organ to come in and modify responses is the thyroid, and a little later the suprarenals At this period from 120 to 125 hours, there is an enormous differentiation in the sympathetic nervous system Only very much later do the sex organs apparently come into the neural circuit

Neuraxial Differentiation of the Fibers from the Horizontal and the Fibers from the Vertical Semicircular Canal

Dr Charles K Mills and Dr Isaac H Jones, Philadelphia Cajal has shown histologically that fibers from the vestibular portion of the eighth nerve enter Deiters' nucleus and continue from the inferior cerebellar peduncle into the cerebellum itself We believe that (1) this path includes the fibers from the horizontal semicircular canals exclusively, and that (2) the fibers from the vertical canals have an entirely different course The former are confined to the oblongata, while the latter ascend into the pons In twenty-eight cases in which the labyrinths themselves and the eighth nerves were normal and the horizontal canals gave normal reactions, the vertical canals failed in some or all of the well known responses That the labyrinths themselves were normal was made probable by the presence of perfect hearing, and corroborative evidence of neuraxial lesions was additional confirmation In five cases, stimulation of the vertical canals produced no nystagmus, no vertigo, no past-pointing and no falling, and yet violent projectile vomiting occurred This showed that the vertical canals themselves were functionating, in fact, there was even a hyperactive response of the tenth nucleus to the stimulation of the canals In one case in which the lesion was clearly thrombosis of the right posterior inferior cerebellar artery, the right horizontal canal failed to respond normally, whereas reactions from the right vertical canals were normal Therefore, a central differentiation of the fibers from the different canals must exist In a case of Mills the fibers from the vertical canals failed to respond, while those from the horizontal canals reacted In this case a necropsy was obtained and a microscopic examination with serial sections was made It shows a glioma of the upper part of the pons, the lower half of the pons and the oblongata being normal This proves that the vertical canal fibers extend as far at least as the middle of the pons In a case of Dr T H Weisenburg, symptoms of involvement of the right sensory portion of the fifth nucleus and the right sixth nucleus and sensory symptoms in the left extremities indicated a lesion in the right side of the pons posteriorly in the region of the middle cerebellar peduncle In this case, stimulation of the right vertical canals failed in all responses, whereas the right horizontal canal and all the canals of the left ear gave normal reactions In our experience, interruption of the impulses from the vertical canals is produced by tumors of the cerebellopontile angle, internal hydrocephalus causing pressure on the floor of the fourth ventricle, and intracerebellar tumors causing pressure on the pons

Sensory Disturbances of Cerebral Origin

Dr Alfred Gordon, Philadelphia I find that the generally adopted views concerning sensory disturbances of cerebral origin do not always present the real condition For example, in one of my cases there was a large hemorrhage strictly limited to the parietal lobe, nevertheless, there was a hemiplegic condition on the opposite side Also in a case with involvement of the very posterior portion of the internal capsule, which is supposed to be purely sensory in function, there were no sensory disturbances at all during life My conclusions are that, in spite of the generally accepted views concerning sensations of cerebral origin, certain conservative reservations should be made whenever diagnostic deductions are to be made

DISCUSSION

Dr David I Wolfstein, Cincinnati A colored man came into our receiving ward but was not admitted because nothing could be recognized He came a week later and we found that he had localized convulsion of the face and arm and there was very complete arteriosclerosis He also had a loss of the position sense and impairment of the localizing sense The Roentgen rays showed that he had been stabbed in the head with a penknife and that a piece of the blade was extending into the precentral convolution The blade was extracted, and the man recovered promptly from the convulsions, but the arteriosclerosis and the disturbance of the sensations remained as before

Dr H H Hoppe, Cincinnati I recall a case of tumor in the arm center in which the first manifestation was pain in the tip of the finger, this disturbance of sensation preceding the jacksonian seizures The tumor was located in such a way as to cover both the ascending and the parietal lobe It was impossible to tell where it originated

Tic Spasmodique Produced by Cerebellopontile Tumors

Dr Harvey Cushing, Boston A patient was sent to the Brigham Hospital with the diagnosis of right parietal tumor producing jacksonian attacks of the left face He was conscious and could turn his head even though the attack was going on He was very certain on two or three occasions that the attack, and the spasm with the sensory disturbance, which he said came with it, had spread into the arm and side A careful examination made it quite evident that this was a cerebellopontile tumor of the usual type He was operated on and a tumor was found relatively early and removed, so far as one is justified in removing these things, leaving the capsule. In a series of from fifty to sixty pontine cases this was the only case in which I observed these definite attacks, and this began originally as nothing but a little blepharospasm of the left eye The patient was having attacks every ten minutes when he came to us They subsided after the operation Since this I have seen one other example of almost exactly the same kind

DISCUSSION

Dr J Ramsay Hunt New York In my papers on the sensory route of the facial nerve I have emphasized the production of reflex spasms of the face. I have had a series of cases of reflex quiverings and spasms of severe degree. In one case there was a spasm only of the auricular mechanism Evidently only certain cells of the facial nucleus were in a state of excitability Therefore I do not think that these cases necessarily depend on pressure on the pons

Dr William G Spiller, Philadelphia Some years ago Dr Mills had a case of spasm confined to one side of the face which at necropsy showed tumor of the cerebellopontile angle. I had a case of a man struck on the right side of the forehead He said that the eyelids of both sides were affected Dr Jones concluded that there was a tumor of the cerebellopontile angle, and this was confirmed by necropsy

Dr. W B Cadwalader, Philadelphia In a case which I have observed there were clonic movements of one side of the face without loss of consciousness We decided that there was probably a cerebellopontile growth Necropsy showed an endothelioma a short distance anterior to the eighth nerve

Stock-Brainedness The Causative Factor in the So-Called Crossed Aphasias

Dr. Foster Kennedy New York The cause of the indecision in regard to the location of the speech centers and, therefore the causation of aphasia, lies in the fact that apparently irrefragable evidence can be produce by the protagonists of each of the different views The case used to disprove the validity of Broca's area only impugns the theory of constant conjunction of right-brainedness and left-handedness or vice versa. I want to suggest that the simple statement that a given patient is right-handed or left-handed is not adequate. After investigating the question of a patient's handedness only by investigating also the prevalence of the type of handedness in his stock shall we be able to throw some light on a very obscure chapter of neurologic medicine In the literature of aphasia one finds that but few cases disagree with the general hypothesis that in right-handed persons the centers of language are situated on the left side of the brain In the few instances in which aphasia has resulted from injury to the right brain some anomalous and adventitious circumstance has usually been brought forward to account for the situation. It would appear that this trend when present in the stock may produce in a few right-handed individuals of the sinistral stock a condition of brain similar to their collateral relatives and ancestors with the result that the speech area in such persons becomes developed in an ectopic position

DISCUSSION

Dr. Hugh T Patrick, Chicago About thirty-three years ago Dr Janeway gave us a sort of rule of thumb in deciding on who was right-handed and who was left-handed that is, that a left-handed person must be a left-handed writing person All other activities are of less importance

Dr. Joseph Collins, New York It is currently reported that the majority of children are left-handed However credible statistics show that only about 5 per cent. of adults are left-handed It is quite possible that some of these cases referred to by Dr Kennedy are exceptions to the rule, which is that the speech area of left-handed individuals is on the right side of the brain If Dr Patrick will substitute "fighting" for "writing," I will agree with him If a man fights with his left hand he is left-handed If a man does the primitive things of life, the things that are necessary in order for him to continue his activities, he is a left-handed individual I am a left-handed individual, and I do all such things as writing, golfing and drawing, with my right hand, but in striking, at least in doing any of the fundamental things, I am left-handed I am inclined to believe that the executive speech area may be vicariously assumed by areas of the brain adjacent to the usual centers, which will explain the majority of cases which are exceptional to the generally established rule

Dr. E B Angell, Rochester, N Y Some years ago a woman of 32 came to necropsy for brain tumor As a child of 5 she had thrombosis of two thirds of the operculum and part of the motor tract of the left side As a child she had been right-handed As the result of the hemiplegia and loss of the power of the right arm, she had to develop the left hand She regained the power of speech At necropsy were found the remains of the destructive process of the old thrombosis The right side corresponding to the right operculum and the right motor hemisphere were much enlarged The cortex was much thickened showing the influence of the change from right to left as she grew up to womanhood

Dr Charles K. Mills, Philadelphia I think Dr Collins is wrong about this thing of the primitive instinct of preservation This does not have to do with the faculty of speech and development of one or the other hemispheres It is the educational acquirements of the brain that have to do with this If you have the inheritance of speech through many generations with the inheritance of right-handedness, the left-handedness in a given generation is then sort of an accidental deviation and it does not have the force that it would have if the left-handedness had been inherited through many generations

Dr J Ramsay Hunt New York I suggest that Dr Collins is both right and wrong that some of his functions he performs with the cortex and some with the globus pallidus Many of the acts, for instance, fighting, must be referable to the automatic mechanism

Dr. Bernard Sachs, New York It is a fact that the majority of children are in the ordinary sense born ambidextrous, and the important thing is that most persons become later in life absolutely right-handed Another point is that in the loss of speech the defect is associated with loss in the two hemispheres about equally, and it is only later in life that the preponderance of the left hemisphere has become well established I believe that there are differnt groups of cases The ordinary child born ambidextrous can be made a right-handed child There are some persons who never can be made right-handed I believe the larger number of persons are right-handed because they are made so by education

Dr. William G Spiller, Philadelphia A child born right-handed was burned in a gas flame and was unable to use the right hand for five or six weeks During that time he used the left hand and, when the bandage was removed continued to use the left hand It required training to induce the child to resume the use of the right hand Undoubtedly if the effort had not been made to train the right hand the child would have continued using the left hand

Dr. Francis X Dercum Philadelphia If my recollection serves me correctly, the right side of the child is larger at birth I think there is more muscle tissue in the right side than the left. It cannot be merely a matter of training, but, if the right hand is injured, the left hand is trained

Dr. Harvey Cushing Boston It may be of interest to call attention to the fact that right-handedness and left-handedness goes back into other forms of life than mammals In certain shells perhaps one out of 10,000 there is a left-handed spiral. Then, too, I believe that parrots are right-handed or right-clawed, as a rule

Dr. Alfred Reginald Allen, Philadelphia The blood supply of the human being and most mammals and vertebrates is not symmetrical with the vertical axis It is probable that the left side of the brain may get a better blood supply than the other side of the brain

Dr Isaac Adler, New York I have been making some cranial measurements and I ran across a peculiar relation of the right hemisphere In the right-handed the right parietal lobe is more prominent than the left In the left-handed person it is not so It is about equal The conclusion is that most left-handed persons, therefore, are ambidextrous

Amyotrophic Lateral Sclerosis

Dr John H W Rhein, Philadelphia The subject of this report was aged 56 The symptoms were atrophy of both arm muscles, including the small muscles of the hand, the flexors and the extensors of the forearm, the biceps, triceps, shoulder girdle, pectoralis and serratus magnus There were fibrillary tremors of both arms Both sides of the tongue were atrophied, the knee and arm jerks were exaggerated, but there was no Babinski sign or spasticity The Wassermann reaction was positive Death occurred about a year after the onset

DISCUSSION

Dr F R Fry, St Louis Some years ago I reported a classical case of Friedreich's ataxia in a girl of 12 or 15 years of age At a later period the mother of this girl, who was then about 42 years of age, developed amyotrophic lateral sclerosis I simply mention that little coincidence as possibly interesting from an etiologic standpoint

Dr Samuel Leopold, Philadelphia I have reported a similar case The patient died within two years I found some round cell infiltration In about one third of these cases, syphilis plays a very important role

Diffuse Endothelioma of Spinal Cord

Dr Peter Bassoe, Chicago, and Dr C L Shields, Salt Lake City The patient, a girl of 16 years, was taken with headache, vomiting and dizziness eight months before death Later there were failing vision, two weeks of strabismus and finally complete blindness Hearing also was lost The optic disks showed secondary atrophy, and the tendon reflexes were lost The spinal fluid showed lymphocytosis and increased albumin There were convulsive seizures during the last two weeks before death The necropsy revealed the unusual condition of a diffuse grayish-white thickening of the pia along the entire cord, most marked posteriorly Histologically, this tumor proved to be endothelioma

(To be continued)

20 Toxicity of Novocain Epinephrin Injected Intravenously J R Eastman, B Erdman and H K Bonn, Indianapolis

9 **Removal of Bullet from Pericardium**—The principal feature in this case to which Lower calls attention is the method of approach, that is, the division of the cartilaginous attachment to the ribs and of the muscles between the ribs, so as to make, by retraction, a "V" exposure By this method ample room is secured and the ribs are not fractured, a circumstance which retards convalescence and makes it much more painful

10 **Intrahepatic Cholelithiasis**—Lewisohn operated on a case of intrahepatic cholelithiasis in which the preoperative diagnosis was acute gangrenous cholecystitis or perforated duodenal ulcer At operation the gallbladder was found distended to about twice its normal size, not tense, its walls were thin and showed no external signs of inflammation The stomach itself was normal and a careful examination of the duodenum failed to show any sign of ulcer or perforation The liver was enlarged to about one and one half times its normal size and showed extensive adhesions between the upper surface and the diaphragm The whole diaphragmatic surface of the liver felt nodular, these areas were hard, some of them whitish in color On the inferior surface of the liver, toward the anterior border, there was a markedly inflamed area belonging to the right lobe, in this part was seen a small abscess cavity, which had perforated and opened into the free peritoneal cavity At the base of the cavity two small black gallstones were felt, the liver tissue was incised, and the stones removed One of the nodules on the right lobe of the liver was incised, after splitting the capsule, a small hard nodule presented itself, about the size of a pea, the mass was whitish and hard (fibrous tissue?) From the center of this mass four small, black gallstones were removed They were exactly like those which had been found on the under surface of the liver The gallbladder contained about 30 c c of a turbid fluid and one-half dozen yellowish gallstones The mucosa was only slightly inflamed and not thickened

11 **Correcting Stomach Dilatation in *Gastroptosis***—The method devised by Behan is as follows The stomach is exposed and a flap of serosa is freed from its anterior surface The flap (½ inch wide) extends from the lesser curvature downward obliquely toward the greater curvature and fundus for about 3 to 4 inches This flap is then inserted in a reversed direction through two flaps raised from the subjacent muscularis and is sutured in place The raw surface is puckered in and the wound closed The stomach in one instance was removed and examined after this operation It was remarkably decreased in size At the area of operation there was a very long ruga which projected into the lumen of the stomach After the plication the muscle contracted and threw the mucosa into deeper folds To sight and touch the gastric muscle was absolutely normal Behan has used this method on two patients and so far the results have been very satisfactory

14 **Perforating and Varicose Ulcers of Leg**—The only modern surgical method of treatment in Smits' opinion that reckons with etiology is local treatment of the sore combined with stretching or laceration of the nerve, in the region in which this sore is situated In the twenty-five cases of perforating ulcer of the foot cited by Smits the mere local surgical treatment was shown to be useless in all these cases,

even when combined with an absolute rest cure The same surgical treatment combined with a nerve operation, whether executed once or repeatedly, always led to cure Eighteen cases of varicose ulcer similarly treated are cited Locally he applied a liquefied medicated gelatin made as follows Dissolve in a water bath 20 parts of gelatin in 40 parts of water To this add 10 parts of glycerin, mix with 15 parts zinc oxid previously ground up with 15 parts glycerin and add water enough to make 100 parts Smits spreads a thick layer of this liquefied medicated gelatin over the leg and covers this while still wet with a thin layer of cellulose wadding which immediately sticks and forms an immovable dressing Over the layer of cellulose wadding a bandage of well starched gauze is placed The patient remains in bed until the dressing is thoroughly dry

18 **Preoperative Treatment of Hands**—As a result of their investigations Whiting and Slocum conclude that a solution consisting of acetone alcohol and one of the coal tar disinfectants of a high phenol coefficient is more efficient than any other agent used for skin sterilization In such a solution the acetone (dimethylketone) acts as a solvent of the fatty or oily material of the skin and thus aids in exposing the bacteria to the germicides The alcohol acts as a solvent it has the power to penetrate into the cracks and crevices of the skin through its ability to decompose and remove small particles of air that may be present it is germicidal in solutions as weak as 30 per cent With its strongest germicidal powers in solutions ranging from 60 to 70 per cent it also acts as a good vehicle The coal tar disinfectant that may be used acts simply as a powerful germicide destroying all bacteria with which it comes in contact in a length of time varying with its coefficient and the degree of dilution The advantages of such a solution are many Patients do not complain of any irritation following its use although it causes a burning sensation when used on the scrotum It does not stain the skin It reduces to a minimum the time consumed in preparing the field of operation and its method of application is the simplest It may be used on a wet or dry skin for emergencies or for cases in which the consumption of time in preparing the patient is not of great moment There is no exfoliation of the skin as is seen after the use of iodin nor is there any blistering It may replace all other solutions in sterilizing the hands although its continuous use causes some irritation in some instances, in others no effect is noticed others say the application of the solution gives rise to a decided feeling of warmth The solution may be used repeatedly any collected detritus being removed by filtration The authors suggest that a solution consisting of 35 per cent acetone, 1 or 2 per cent of a coal tar disinfectant of a high coefficient with enough alcohol to make 100 per cent would answer the purpose. The method of application consists in rubbing the field of operation for two minutes with a piece of gauze saturated with the solution after either a wet or dry shave A warm cleansing tub bath is always advisable when not contraindicated

28 *Basal Metabolism in Obesity J H Means Boston
29 *The Typhoidin Reaction C R. Austrian and A. L. Bloomfield Baltimore

21 **Multiple Abscesses of Brain in Infancy**—The case reported by Holmes represents a rare condition multiple large abscesses in the hemisphere of an infant under 2 years of age It ran its course under the picture of chronic internal hydrocephalus That chronic internal hydrocephalus of the communicating type was not present was shown clinically by the phenolsulphonephthalein test The condition found at necropsy resembled closely that of multiple pyogenic abscesses of the left hemisphere It was not possible however, wholly to exclude multiple tubercles which had undergone puriform softening Microscopically, the case is noteworthy in the unusual number of Gluge's corpuscles that are present

22 **Experimental Observations on Pineal Gland**—The results of an experimental study are given by Horrax He found that total experimental pinealectomy is possible in guinea-pigs and rats Pinealectomized male guinea-pigs show a hastened development of the sexual organs, manifested before maturity by a relative increase in size and weight both of the testes and seminal vesicles, over control pigs of the same litter Histologically the testes and seminal vesicles of these animals if taken before the age of sexual maturity show a more advanced physiologic state than their controls The pinealectomized females appear to show a tendency to breed earlier than controls of the same age and weight For several reasons young rats are likely to prove better subjects for experimental pinealectomy than young guinea-pigs and some evidence of hastened maturity has been obtained in this species

23 **Clinical Observations on Pineal Gland**—Clinical study of three cases of supposed pineal tumor demonstrated that tumors of the pineal gland in children occurring before the age of puberty usually give rise to a syndrome characterized by precocious adolescence. In the first case there were no positive means of knowing whether or not the pineal is the organ mainly at fault The history and findings, however, are suggestive and conform to the symptom complex of Frankl-Hochwart except that the patient was a girl 11 years of age Adiposity though not great, was present to a definite degree this with the other points making the case very similar to Marburg s There was an increase in the eosinophilic leukocytes The second patient was a boy 7½ years of age In this instance Horrax was unable to say what part the pineal may or may not be playing in the syndrome Clinically however the symptom complex was similar to that characterizing a pineal lesion but without adiposity The sexual side of the picture is decidedly in the foreground There has been little intellectual attainment the latter sphere having been greatly limited by the boy s environment In the third case the lesion was certified in full The patient was a boy 12 years of age There was a precocious adolescence intracranial symptoms with diagnosis of tuberculous meningitis xanthochromia Necropsy revealed struma of the pineal gland A striking feature of the tumor as a whole was the great number of lymphoid cells it contained These were present both in large masses grouped together and also as scattered elements throughout the growth without definite arrangement This enormous development of lymphoid tissue in a patient 12 years of age brings out the possibility of associated lesions elsewhere in the body especially in connection with the thymus and lymph glands The limited necropsy prevented studies of these tissues

25 **Sino-Auricular Block Due to Tobacco Poisoning**—A study of the history and clinical course of the two cases cited by Neuhof showed that the two distinct types of arrhythmia sino auricular block and ventricular extrasystoles were apparently caused by two different factors, the former by tobacco the latter probably by myocarditis and nephritis The sino-auricular block disappeared very soon after smoking was stopped the extrasystoles only when compensation was fully restored The cases seem to substantiate in a degree the results of animal experimentation In Case 2 the extrasystoles were the result of decompensation The sino-auricular block represented the effects of nicotin poisoning on the vagus alone Patient 1 had no organic disease. The moderate acceleration interspersed with irregularly occurring sino-auricular block was apparently a clinical prototype of the two opposed experimental effects of the tobacco alkaloid on the vagus and accelerator

28 **Basal Metabolism in Obesity**—According to Means the majority of obese subjects show no alteration in the basal

metabolism, as expressed in terms of their surface area, even though the obesity is of a most extreme type Occasionally a slight reduction occurs and in such cases clinical evidence of disturbed internal secretion is present

29 **Typhoidin Reaction**—The typhoidin reaction carried out by Austrian and Bloomfield in sixty-six individuals failed to furnish data by means of which it was possible to differentiate between those who had neither had typhoid nor received prophylactic vaccination and those who had either had the disease or had been artificially immunized against it

42 **Compressed Air (Caisson) Disease**—A typical case of caisson disease eventuating in recovery is reported by Keyser It is shown that the various congestion theories are quite fully refuted by a simple application of certain fundamental laws of physics, while the gaseous theory is fully supported by these same laws The characteristic pains and rigidity are considered to be due largely to the irritative nature of the cord lesions The relief of urinary retention by the administration of pituitary extract is of special importance for the reason that cystitis is a most serious complication in the disease The onset of recovery following lumbar puncture is an interesting observation in this case

54 **Antagonistic Action of Negative Serum on Wassermann Reaction**—In the clinical application of the Wassermann reaction it is generally agreed that there are a relatively large number of cases of syphilitic infection especially in the tertiary stage, in which the test is negative It would evidently be desirable to secure some method in which a negative reaction would justify the exclusion of syphilis The possibility suggests itself to Sellards and Minot that syphilis could be excluded if the serum under examination *gives strong hemolysis in the presence of a trace of positive* serum Indeed, when no trace of hemolysis occurs under these circumstances it is desirable to search especially carefully for evidences of syphilis While it is certainly not desirable to increase the sensitiveness of the Wassermann reaction by reenforcing the antigen any further or by increasing the amount of patient's serum which is used, it is still possible that the addition of a trace of positive serum to a negative one might act in a very different direction and, by neutralizing the antagonistic property of normal serum, bring out obscure or weak reactions This would be of *interest, not in the routine Wassermann test, but only for* purposes of experimental study

56 **Agglutination Reaction with Leprosy Serum.**—The agglutinin present in the serum of the human subject affected with leprosy is usually low in titer and inconstant in its action The employment of this procedure, therefore, has proved of no avail in serving to authenticate any of the various cultures isolated from the leprous lesion of the human as the Hansen bacillus The serums derived from rabbits inoculated with various bacillary antigens yield agglutinins likewise inconstant in amount and erratic in their action Serums derived from these inoculated animals do not serve to differentiate the various species employed in these experiments, but suggest a group relationship Until some further refinement in these procedures is devised, Harris and Lanford assert that but little reliability can be placed on this type of test as a means of identification of any culture isolated from the lesion of leprosy as the bacillus of Hansen.

57 **Method of Producing Potent *Precipitin Serum***—Smith points out that in many places human blood, or human blood serum, cannot be readily obtained When a quantity of blood can be gotten at once, such as is present in a placenta, it may be precipitated with ammonium sulphate and kept on hand for a long time, at least nine months, and no doubt indefinitely The precipitated protein is capable of producing a potent precipitin rabbit serum, when injected intraperitoneally The danger to the animal to be injected is reduced by using this precipitate, as a smaller quantity of material is injected and the precipitate thus prepared is sterile or nearly so The precipitate can be kept on hand and be readily used in case of emergency

60 **Blood Lipase in Health and Disease**—The serum of patients suffering from bacterial diseases, Sagal claims, show a slight increase in enzyme activity, while the serum obtained from sufferers of diseases of nonbacterial origin show a slight depression Bile stained serum and the serum from hepatic cirrhosis show marked decrease in enzyme activity Lipase activity gradually decreases with increasing age Variation of lipase activity in diseased conditions, as shown by the hydrolysis of ethyl butyrate, are so small as to be devoid of diagnostic or prognostic value

62 **Study of Acidosis, Action of Alcohol as *Antiketogenic* Agent.**—In three healthy subjects studied by Higgins, Pea-

body and Fitz a carbohydrate free diet caused the development of varying degrees of acidosis The acidosis was shown by a lowered CO tension of the alveolar air, by an increased urinary excretion of ammonia nitrogen and of acetone bodies and by the increase titratable acidity of the urine The acidosis was accompanied by subjective sensations of malaise, an increased oxygen consumption, a negative nitrogen balance increased pulse rate and increased ventilation Alcohol given to the subjects on this diet in dosage comparable to that used for clinical purposes did not stop the progress of the acidosis or show any antiketogenic action Coincidental with its administration there was further increase in the oxygen consumption, and in the disagreeable subjective symptoms

Journal of Nervous and Mental Disease, Lancaster, Pa

May XLIII No 5 pp 393-488

63 *Tabes Dorsalis Pathologic and Clinical Study of Two Hundred and Fifty Cases B Lucke Philadelphia
64 Hydromyelia and Hydroencephalia Report of Case A Gordon Philadelphia
65 *Abnormal Relation Between Liver and Brain Weights in Forty Two Cases of Epilepsy D A Thom Palmer Mass
66 Case of Atypical Multiple Sclerosis With Bulbar Paralysis S Krumholz Chicago
67 Case of Peripheral Neuritis With Korsakow's Symptom Complex A A Wilson Washington, D C

63 **Tabes Dorsalis**—The symptoms and pathologic findings of 250 cases of tabes dorsalis are analyzed by Lucke Two hundred and seven or 82 8 per cent, are white males, 29 or 11 6 per cent are white females, 13 or 5 2 per cent are black males, 1 or 0 4 per cent is a negress Only 141 or 56 4 per cent admitted syphilis The average period of years was 15 34 which elapsed between primary sore and beginning tabetic symptoms There were no cases of so-called juvenile tabes Lancinating pains somewhere in the body, lead the percentages (31 2) of the initial symptoms and occupy first place in the total (71 6) In the 169 cases (67 6) which showed sphincter disturbances the rectal sphincter was affected in 70 and the vesical sphincter was affected in 143 Girdle sensation was present in 31.2 per cent Loss of sexual power was noted in 11.2 per cent Anosmia and deafness were each observed in 2 cases or 0.8 per cent Insanity, other than paresis in locomotor ataxia, occurred in 6 cases or 2 4 per cent

Knee jerks were absent in 90 per cent Romberg's phenomenon was present in 241 cases or 96 5 per cent Arthropathies occurred in 23 cases or 9.2 per cent, in 7 cases there was bilateral arthropathies The joints affected were right knee joint in 9 cases left knee joint in 5 cases, both knee joints in 4 cases right knee joint and metatarsophalangeal joints in 1 case both ankle joints in 2 cases, left ankle joint in 1 case In one case Charcot joint (knee) occurred as the first symptom of tabes Spontaneous fracture occurred in but one case, a woman who suffered about ten years after the onset symptoms, a fracture of the femur This fracture was the result of a slight fall The fracture caused but little, if any, pain At the present time, six years after fracture union has not taken place Malperforant was found in 8 cases or 3.2 per cent. The perforant ulcer always occurred on the foot Footdrop occurred in 9 cases or 3 6 per cent. Hemiplegia and tabes occurred in 6 cases or 2 4 per cent.

Visual disturbances occurred in 109 cases or 43 6 per cent. of these, failing eye sight occurred in 63 cases or 25.2 per cent. diplopia occurred in 46 cases or 18 4 per cent, optic atrophy occurred in 37 cases or 16 0 per cent, nystagmus occurred in 23 cases or 9.2 per cent It is of interest to note that in one of two blind cases Romberg's sign is not so great with eyes open while he promptly will sway and even fall to the ground if he closes his eyes The other case has a marked Romberg's which is more decided with eyes closed Typical Argyll Robertson pupil occurred in 200 cases or 80 per cent, sluggish reactions or no reactions occurred in 32 cases or 12 8 per cent., normal reactions occurred in 18 cases or 7.2 per cent, unequal pupils occurred in 86 cases or 33 6 per cent, irregular pupils occurred in 34 cases or 13 6 per cent, unequal and irregular pupils occurred in 20 cases or 8 per cent, ptosis of both eyelids occurred in 17 cases or 6 8 per cent, ptosis of left eyelid occurred in 16 cases or 6 4 per cent, ptosis of right eyelid occurred in 4 cases or 1 6 per cent, and paresis of eye muscles occurred in 30 cases or 12 0 per cent

65 **Abnormal Liver and Brain Weights**—In twenty-six (62 per cent), in this series of forty-two cases studied by Thom, the brain outweighed the liver Of the sixteen cases in which the relative liver and brain weight was normal, in only two were the weights of the liver and brain both within the normal limits in the same case namely, forty of the forty-two cases studied revealed either an abnormal relation between the liver and brain weights, or that one of the organs was of abnormal weight In some cases both conditions were true The most common gross abnormalities named in order of their frequency were as follows atrophy of liver, atrophy of brain overweight of brain (probably due to edema or hydrocephalus), hypertrophy of liver

Journal of Pharmacology and Experimental Therapeutics, Baltimore

May VIII No 5 pp 205 271

68 *Liberation of Epinephrin From Suprarenal Glands by Stimulation of Splanchnic Nerves and by Massage G N Stewart, J M Rogoff and F S Gibson Cleveland
69 *Rôle of Liver in Acute Polycythemia Relation of Plasma Volume to Number of Erythrocytes Per Unit Volume of Blood P D Lamson and N M Keith Baltimore
70 *Action of Certain Volatile Oils on Isolated Intestinal Segments A L. Muirhead and H F Gerald Omaha
71 *Pharmacology of Ureter Action of Drugs Affecting Sacral Autonomics D I Macht, Baltimore.

68 **Liberation of Epinephrin from Suprarenal Glands**—It is shown by the authors that the response of the denervated eye to stimulation of the peripheral end of the splanchnic nerves is due solely to the passage of a substance in the blood stream from the suprarenals to the eyeball When the venous path is blocked the response fails, but appears on releasing the block When the heart is stopped by stimulation of the peripheral end of the vagus, stimulation of the splanchnics produces no effect on the eye. But on allowing the heart to beat again, the eye response occurs at approximately the same time from the moment of reestablishment of the circulation, as the time interval between stimulation of the splanchnics and the response with the circulation going on normally When the circulation is slowed without being stopped, the interval between the beginning of stimulation of the splanchnics and the appearance of the eye response is correspondingly increased When epinephrin is injected into the left renal vein, or into the central end of the femoral vein, in suitable amount to produce an eye response approximately equal to that produced by a given stimulation of the splanchnics the interval of time after which the response follows is sensibly the same for epinephrin injection as for splanchnic stimulation When the aorta is clamped and the splanchnic then stimulated, a response may be obtained in the eye while the clamp is still on, or only after its removal, or both during the application and after removal of the clamp

Circulation time measurements show that there is always more than sufficient time for a substance to have been carried in the blood from the suprarenals to the eye before the appearance of the eye reactions The minimum period of stimulation of the splanchnics needed to liberate sufficient epinephrin to elicit a response in the denervated eye is very brief (a fraction of a second) Massage of one or both suprarenals causes definite eye response in an animal in which stimulation of the splanchnics has been causing it, and at the same interval of time. When, after repeated excitations of a splanchnic nerve, the reaction on the eye ceases to be obtained it can still in general be elicited by massage of the corresponding suprarenal But this reaction is soon exhausted

69 **Rôle of Liver in Acute Polycythemia**—It has been demonstrated by Lamson and Keith that when the hepatic artery is ligated, the intravenous injection of epinephrin causes a decrease in plasma volume, without an increase in the number of erythrocytes per unit volume of blood Further plasma volume and the number of erythrocytes per unit volume of blood may vary independently of one another

70 **Action of Volatile Oils on Intestinal Segments**—The following oils were studied by Muirhead and Gerald pennyroyal, tansy, wormwood, turpentine, rue, anise, savin and thymol A number of these oils produce quite marked stimulation of isolated intestinal segments when applied in dilutions of 1 to 50,000 to 1 to 25,000 This is especially true of oil of anise, oil of turpentine and oil of wormwood All of the oils produced relaxation of intestinal segments when applied in dilutions of 1 to 5,000 to 1 to 10,000

71 **Action of Drugs Affecting Sacral Autonomics**—Macht found that pilocarpin, physostygmin, muscarin, pseudomuscarin and cholin, in suitable doses all stimulate the rate and force of the ureteral contractions and increase the tonus of the excised ureter Large doses of pilocarpin may, however, secondarily paralyze that organ The pressor action of pilocarpin, physostygmin and muscarin, is not inhibited by previous exhibition of ergotoxin Atropin in sufficient (rather large) doses, inhibits the contractions and decreases the tonicity of the ureter Small doses of atropin may produce, though not invariably, a primary stimulation of the ureteral contractions The same effects as in the ureteral preparations described by the author, were noted in rabbits by observing the ureters in situ, after administration of pilocarpin, physostygmin and atropin The behavior of the ureter toward the drugs studied, Macht says, gives pharmacologic proof of its innervation by the sacral autonomics, and is also of some practical interest

1 Hearing Tests in School Children M Yearsley
2 *Nephritis Without Albuminuria J P Parkinson
3 Case of Dyspituitarism in Girl, Aged Fifteen Years S Stephenson
4 Retrospect of Otology, 1915 M Yearsley

2 **Nephritis Without Albuminuria**—The case cited by Parkinson began as pneumonia in a boy of 3½ years of age A few days after his recovery slight edema appeared on the face, and the next day the face was *extremely swollen*, as also were the arms, hands, feet and legs, and the wall of the trunk There was no evidence of fluid in the chest or abdomen From now the urine was examined daily, but no albumin was ever found Microscopically a few granular and hyalin casts and an odd red corpuscle or two were found on centrifugalizing The amount of urine passed daily was normal, and fairly abundant urates were deposited on standing On the third day the patient got very stupid, but not exactly drowsy The blood pressure on this date was 90 mm The edema began to disappear after three or four days under hot air baths and saline purgatives and after ten days all casts and blood had disappeared from the urine, only a few epithelial cells from the bladder being seen on centrifugalizing Parkinson believes this child to have had an attack of acute nephritis following but not due to pneumonia causing edema and the presence of casts and blood cells in the urine, but without albuminuria

11 Therapeutic Value of Hypochlorous Acid R F Cordova
12 Simple Method for Intravenous Injection of Eusol J M Graham

6 **Congenital Atresia of Duodenum**—Ernst's patient was only 12 months old From the first the child always vomited after suckling On the third day it took the breast more actively than at first, but two or three hours later it began to vomit, with almost explosive violence Very little urine was passed, and the motions were limited to a small amount of typical meconium, without a particle of digested milk The child was treated both with castor oil and enemas Rectal examination revealed no abnormal condition of the bowels The child lost weight rapidly Ernst made a diagnosis of high-seated intestinal stenosis or atresia and suggested an operation On opening the peritoneum the dilated stomach protruded into the wound, and was traced along the dilated pylorus into the duodenum, which was uniformly of about two fingerbreadths in width, so far as it could be traced to the upper side of the transverse mesocolon But below the colon, where the intestine reappeared, at the flexura duodenojejunalis, it was seen to have collapsed to the caliber of an ordinary pencil, about 8 millimeters in diameter The remaining part of the small intestine was normal Ernst made a duodeno entero-anterior anastomosis—that is to say, a coil of small intestine about 4 inches below the flexura duodenojejunalis was drawn up in front of the transverse colon, and united to the duodenum about the junction of the pars superior and pars descendens Anastomosis to the lower part of the pars descendens was impracticable The child made a complete recovery and is now alive and well

19 *Subacute Anterior Poliomyelitis A W Harrington and J H Teacher

19 **Subacute Anterior Poliomyelitis**—The patient whose case is cited by Harrington and Teacher was an elderly woman who presented a flaccid paralysis beginning in the peroneal group extending rapidly to the upper extremities, and finally involving the muscles of respiration The paralysis appeared first and later atrophy of the affected muscles became marked No fibrillary tremors were observed Repeated and thorough examinations showed that there were no disturbances of sensation beyond occasional shooting pains The sphincters were not affected The reflexes were early abolished An examination of the electrical reactions on admission showed reaction of degeneration fully developed in the affected muscles of the left leg and incomplete in the right leg The Wassermann reaction was not ascertained, but there was no history or suggestion of syphilis The patient died from involvement of the diaphragm and intercostal muscles the duration of the illness being probably less than a year Clinically the diagnosis lay between peripheral neuritis and anterior poliomyelitis The pathologic report was wholly in support of the latter diagnosis The principal features were the advanced degenerative changes in the ganglion cells of the grey matter of the spinal cord, and to a less degree in the medulla and pons and the absence of tract degenerations and peripheral neuritis A second patient, a woman of 48 years exhibited a flaccid paralysis beginning in the peroneal group of muscles, rapidly extending to the upper extremities, and finally involving the muscles of respiration The paralysis preceded the atrophy Reaction of degeneration was present but there were no fibrillary tremors There was no disturbance of sensation beyond occasional shooting pains in the right leg The duration of the illness was less than one year The diagnosis was indicated by the somewhat selective nature of the palsy, by the distinct atrophy which followed and by the complete absence of sensory disturbance Clinically, the case could be definitely distinguished from progressive muscular atrophy and peripheral neuritis Pathologically there was degeneration of the lower motor neurones The case probably should be regarded as a subacute poliomyelitis

25 Clinical Manifestations of Gas in Military Mines C E Sundell
26 Cases of Foreign Bodies in Bladder Resulting from Gunshot Wounds G G Turner
27 *Ulcerative Stomatitis K Goadby

24 **Novocain in Spinal Anesthesia.**—Holman emphasizes the fact that spinal anesthesia is a method which must be employed with scrupulous care and attention to detail He says that it is more suitable for use in hospitals in which the nursing staff is familiar with the technic and after-treatment, than it is for casual operations in private practice Like many valuable operations it has sometimes obtained a bad reputation through improper performance

27 **Ulcerative Stomatitis**—Ulcerative stomatitis, often preceded by or accompanied with sore throat, is appearing sporadically among the troops in France as well as in some of the English camps A smear preparation made by Goadby from the gums, cheeks or throat and stained by Giemsa's method showed innumerable bacteria of two morphologic forms (1) *Bacillus fusiformis* and (2) spirochetes both gram-negative Stained by Leishman's stain or Giemsa the fusiform bacilli were seen to be diplobacilli 6 to 7 microns in length, with pointed extremities, the thickened ends being in apposition with a small clear area between somewhat resembling the sheath form of the *Bacillus diphtheriae* The organism is longer and larger than the diphtheria bacillus and is slightly curved, plasmolysis is common The second or spirillum form closely resembles the spirillum of relapsing fever as seen in blood films, it is wavy in outline irregular in form and without the characteristic regular 'screw" form seen in *Spirochaeta pallida* Many of the organisms show unmistakable spiral form, the turns' of the thread are but four to six in number, the ends may be pointed, but the organism is usually about the same diameter throughout, in hanging-drop preparations from the tissue it is not motile The organism is an obligatory anaerobe and is also serophile

Quarterly Journal of Medicine, London

April IX No 35 pp 165 256

28 *Experimental Investigation on Diarrhea and Vomiting of Children E Mellanby
29 *Quantitative Determination of Amylase in Blood Serum and Urine as Aid to Diagnosis P Stocks
30 Urticaria Tuberosa of Willan Report of Cases J A Nixon

28 **Diarrhea and Vomiting of Children**—Some years ago an extremely active and toxic substance known as beta-imidazolylethylamin (throughout this paper called β-1) from ergot It is derived from histidin a harmless substance by the removal of carbon dioxid The experimental portion of Mellanby's work was carried out on the assumption that β-1 is one of the most important factors in epidemic diarrhea and vomiting Various hypotheses involving β-1 as the cause of such symptoms can be formulated 1 That in diarrhea and vomiting there is excessive production of β-1 in the intestine due either to (*a*) a changed or increased bacterial flora, (*b*) a changed chemical or physical condition which prevents the absorption of histidin of the food and allows a subsequent increased production of β-1, or to (*c*) a changed condition which allows bacteria acting on histidin to produce a relatively large amount of β-1 rather than innocuous products (such an innocuous product might be beta-imidazolylacetic acid) 2 That in diarrhea and vomiting there may or may not be an increase of β-1, but the β-1, present in the alimentary canal and mucous membrane becomes active in some way and is absorbed into the blood stream at a time when the animal is incapable of resisting its toxic action and rendering it innocuous

The most important results obtained by Mellanby in this research from a practical point of view are as follows First, as regards the absorption of toxins like β-1 from the intestine There is a marked delay in the absorption of toxic substances normally in the intestine when animals are injected with large quantities of fluid Water in the intestine delays the absorption of toxic substances During the digestion of foodstuffs generally, meat milk sugar and fat, there is a delay in the absorption of toxic substances The presence of bile in the intestine delays the absorption of toxic substances Magnesium sulphate of a concentration of 2 per cent or over delays the absorption of toxic substances from the intestine A less concentration of magnesium sulphate has no effect Morphin below the point of being a serious menace to the respiratory center, has no effect on the absorption of toxic substances Secondly, as regards the resisting power of the animal toward absorbed toxic substances The resistance of an animal against toxic substances is very greatly increased by the injection of fluid into the circulation An animal with a diminished amount of fluid and particularly after the loss of a small amount of blood, has little power of resistance against toxic substances An animal s resistance is greatly increased after it has absorbed from the intestine food, and more particularly meat During the digestion of fat, toxic substances absorbed from the intestine have a diminished action, at least for some hours Clinically, a child suffering from diarrhea and vomiting owing to loss of fluid, loss of bile salts, with an empty intestine and in a starving condition, is in an ideal position for allowing toxic substances normally present in the alimentary canal and mucous membrane to be rapidly absorbed and have their full toxic action The association of this disease with a high atmospheric temperature in an epidemic form is to be explained largely by the additional loss of fluid due to evaporation of water, whereby the child keeps down its body temperature Hence, of all treatment in this condition, the one thing essential is to get the volume of body fluids of the child back to normal or above normal by intravenous or subcutaneous injection of saline solution

29 **Amylase in Blood Serum and Urine**—Amylolytic ferment is present in definite quantity 6 6 to 8 units according to Stocks in the blood serum and urine of all healthy individuals, and has also been found in all the body fluids examined The level is practically constant in the blood serum—the level in the urine is subject to diurnal variations due chiefly to the digestive functions The ferment is of pancreatic origin and is absorbed directly by the blood No proof of the action of antiamylase has been found Disease of the kidneys causing any diminished permeability of these organs reduces the amount of ferment in the urine and consequently raises the amount in the blood Any disturbance in the ratio D (blood) D and M (urine) indicates renal insufficiency in all such cases Severe passive congestion also raises the amount of amylase in the blood With these exceptions any increase of the ferment in the blood serum denotes pancreatic mischief The values have been found raised by Stocks in all cases of pancreatic disease the increase depending on the degree of obstruction in any part of the gland or its ducts, and on the acuteness of the condition The highest values were found in a case of acute pancreatitis The estimation of the amylolytic capacity of the blood serum and the urine is a most delicate test of the efficiency of the pancreas, and consequently is a most delicate and reliable test for disease of the pancreas A simplified modification of Wohlgemuth's method was used by Stocks in his work

Annales de Médecine, Paris

March April, III No 2 pp 109 191

31 *Congenital Ectasia of Pulmonary Artery in Man of 65 (Cas d'ectasie simple congenitale de l'artere pulmonaire observée chez un tuberculeux entache de syphilis cerebro spinale presentant des nodules kystiques à distribution symetrique sur tout le corps) E Lenoble

35 *Wounds of the Chest (Notes à propos de 122 cas de plaie de poitrine) M Maillet

31 **Ectasia of Pulmonary Artery**—Lenoble's case was remarkable on account of the absence or mildness of symptoms from the combination of congenital ectasia of the pulmonary artery, cerebrospinal syphilis, pulmonary tuberculosis and about twenty cystic nodules scattered symmetrically over the body The man of 65 was a day laborer and had raised fourteen children One of the cysts was located in the fourth ventricle but the man succumbed to rapid pulmonary tuberculosis

32 **Cobra Venom Hemolytic Test with Nephritis**—Duhot gives the findings in the serum from twenty-six patients with kidney disease and seventy-seven with various other affections The findings were positive with remarkable constancy in the serum from patients with kidney trouble of any kind The reaction was also peculiarly prompt and peculiarly intense in them, regardless of the clinical severity of the kidney disease and of the absence or presence or degree of uremia Positive findings to a lesser degree were obtained also in other conditions in which the lipoid content of the serum is generally augmented, as in pregnancy, diabetes and infectious diseases

33 **Action of Antiseptics in War Wounds**—The research here described was done with eight of the antiseptics currently in vogue, including 1 1,000 mercuric chlorid and Dakin's hypochlorite solution The effect on the leukocytes was estimated from the movements of the granules and the staining properties as well as from the breaking up of the cell Illustrations are given of the aspect of the cell at different periods under the influence of the various antiseptics The alkaline hypochlorite solutions have a prompt dissolving action, liquefying the pus, red corpuscles and blood clots in the wound. This dissolving action is the work of the sodium, and it is annulled by too much boric acid and by salt Living tissue protects itself against this dissolving action by its salt content Irritation of the tissues around a wound being irrigated with hypochlorite solution can be warded off by keeping them covered with a compress moistened with a 20 or 40 1,000 salt solution Charts and tables are given to illustrate this protective action of weak salt solution, effectually protecting the cells and tissues against harm from the hypochlorite solutions Dakin's formula ensures sufficient dissolving action while but slightly irritating normal tissues, and this irritation can be warded off with the 2 or 4 per cent salt solution the hypochlorite and salt just balancing each other

35 **Firearm Wounds of the Chest.**—Maillet's 122 cases illustrate anew the paramount importance of early and prolonged immobilization in treatment of wounds of the chest Gelatin, calcium chlorid and other measures to check hemorrhages were always supplemented by emetin which seemed to have an especially favorable influence in combating a tendency to hemoptysis In one case artificial pneumothorax succeeded when all else had failed These patients are particularly sensitive to getting chilled, and they develop serious congestion at the slightest exposure Quinin was given in the cases with congestion When the effusion could not be tapped, injection into the pleural cavity of 10 c.c. of a 5 per cent solution of methylene blue aided in warding off suppuration.

46 Suppurating Inguinal Glands. (Adenites chancrelleuses.) H Gougerot
47 *Torpid Wounds That Refuse to Heal and Their Treatment (Les plaies atones) F Debat

38 **Antitetanus Serum in Treatment.**—Etienne does not share the pessimistic views of many in regard to serotherapy of tetanus, having had five patients out of six recover under systematic administration of antitetanus serum The men all

had fever except one and this was the one fulminating fatal case This patient proved to be a carrier of tetanus germs as he had no symptoms until under a course of quinin the fulminating tetanus developed Salette has observed similar cases and Vincent has reproduced the same in animals, quinin injections arousing latent tetanus to a rapidly fatal course In Etienne's five other cases, all with favorable outcome, the incubation period had been three six, seven ten or eleven days Tetanus he reiterates, is primarily an infectious disease then an intoxication, and finally a nervous affection The first calls for treatment of the focus the second for antitoxin treatment and the third for chloral and morphin With serotherapy he adds it does no good to shoot at a lion with birdshot," and adequate dosage is the main point

45 **Convenient Mercurial Treatment of Syphilis**—Blechmann says that mercury can be administered by applying a lump of mercurial ointment to the sole of the foot before pulling on the sock or stocking The constant stepping on it forces the drug into the tissues and absorption is so complete that he has had stomatitis follow in some cases The mercury can also be given in the form of a cocoa-butter suppository It may induce transient diarrhea but has no other inconvenience Both of these methods are effectual and discreet while they are convenient for troops on active service, or under other exceptional conditions

47 **Torpid Wounds**—Debat declares that the lack of exercise and the congestion from gravity amply explain the refusal of certain wounds to heal They drag along for months until active measures are applied No drugs are needed merely measures to promote the circulation while warding off harm from gravity congestion Walking with the wounded leg too soon aggravates the gravity disturbances and undoes what has been accomplished The limb should be kept raised enough to counteract gravity and the muscles vigorously contracted five minutes every hour, with daily massage and brief hot air douches, but no drugs

60 Recovery From Severe Puerperal Fever Under Intravenous Injections of Mercuric Chlorid (Sopra un caso di setticemia puerperale guarito con le iniezioni endovenose alla Baccelli.) A. Sofi

57 **Phagocytosis in Acute Infections**—Romagnolo used Stuber's technic for determining the phagocytosis and reports the findings and all details of twenty-four cases of typhoid, meningitis or other acute infectious disease. At first phagocytosis grows less then the defensive forces rally and it increases notably and then gradually drops back to normal The height of the phagocytosis may correspond to the period just preceding the crisis of the disease or it may occur while the fever is at its height or not until convalescence is well under way In one case of erysipelas phagocytosis kept on a very high level even after defervescence and this was explained by the return of the disease, a second attack following on the heels of the first. When the phagocytic power keeps low and grows lower as the disease progresses, the outlook is grave

67 *Epinephrin in Treatment of Nephritis (Cura della nefrite con la soluzione di adrenalina nella pratica di condotta) G B Borelli

66 **Virulence of the Blood in Foot-and-Mouth Disease in Animals**—Cosco and Aguzzi have been conducting research on an extensive scale under the auspices of the national public health service In 116 cattle examined the blood was found virulent during the entire febrile course of the foot-and-mouth disease as virulent as the products of the aphthous eruption The red corpuscles and the serum are equally virulent and the defibrinated blood kept on ice retained its virulence for over a month Red corpuscles thoroughly rinsed from all traces of serum and the serum alone, reproduced the disease on subcutaneous injection of other cattle in a dose as small as 1 c c They regard the red corpuscles thus as ideally adapted for production of a vaccine, and they are now working along this line

67 **Epinephrin in Treatment of Nephritis**—Borelli reports two cases of acute and one of chronic nephritis in which remarkable benefit was realized by epinephrin treatment One patient was a child nearly 5 the others men of 50 and 62 He gave the child sixteen drops a day of a 1 1,000 solution of epinephrin four drops at four hour intervals The adults were given forty drops a day eight at a time Ercolani called attention in 1910 to the benefit from epinephrin by the mouth in nephritis commending the harmlessness, ease and efficacy of this method of treating kidney disease which has proved its usefulness again and again and Borelli s experience has confirmed his statements

69 **Syphilis of the Stomach**—The earlier instalments of Clark's article were summarized in these columns May 20, p 1665 He here gives the minute details of his eleven cases, tabulating them for comparison In three cases the patients had no suspicion of their syphilis, in five the disease had been acquired eleven, fifteen, twenty-seven or thirty years before The stomach had given trouble for three months, eight days, ten months and eighteen months in these cases In one case severe hematemesis on three occasions was the only symptom and mercury soon conquered this In another case the fatal hematemesis was the first sign of anything wrong In conclusion Clark compares his experiences with the twenty-six cases reported by Smithies in The Journal, Aug 14 1915 and the cases referred to by others in the discussion Clark emphasizes the resemblance between the clinical pictures in syphilis and in cancer of the stomach in certain cases

In Clark's latest case there was stenosis of the pylorus from a tumor with much dilatation of the stomach and positive Wassermann reaction, but he was unable to determine whether the trouble was of syphilitic or malignant origin There was no free hydrochloric acid and the man of 55 did not present the cachexia and pallor of cancer, the absence of anemia testifying also against malignant disease The patient was ruddy and there was no trace of metastasis although the symptoms had been noted for eighteen months He refused to take a hospital course of treatment so the diagnosis is still dubious

72 **Sclerosis of the Pulmonary Artery**—The cyanosis of persons with typical sclerosis of the pulmonary artery has won for them in Argentina the name of 'black cardiacs,' *cardiacos negros* Ayerza applied this term to cases of secondary sclerosis and Arrillaga has published eleven typical cases Mayer now adds two more to the list His patients are men of 44 and 53 The cyanosis developed two or four years ago, but for some years before that there had been repeated "colds" and chronic bronchitis with tendency to emphysema and sometimes blood in the sputum and the men's endurance was reduced Nothing in the heart or respiratory apparatus explains this intense cyanosis The fingers and toes show the drumstick shape of chronic pulmonary disease, especially disease of the pulmonary artery, and the fundus of the eyes shows dilation of the veins The blood is approximately normal except for marked lymphocytosis and positive Wassermann reaction Both patients are extremely somnolent and are subject to painful spasms in the chest, a kind of angina pectoris from angioneurotic dyspragia of the pulmonary artery, without participation of the heart The pain spreads from the base of the heart to the depths of the lungs The pulmonary artery is always dilated as also the right ventricle, and the second pulmonary sound is accentuated The absence of edema with the cyanosis, the constant drowsiness, the normal temperature unless there are complications and the Roentgen findings usually readily differentiate the trouble Cupping and digitalis were the chief reliance in treatment and gave much relief

77 **Validity of Will Drawn During Typhoid Fever**—Benitez devotes nearly twenty pages to the evidence on record as to whether a will signed within forty-eight hours of death from typhoid is valid in law He discusses what is meant by typhoid fever, the mental condition of typhoid patients, and the factors which entail death His conclusion is that in the great majority of cases the mind is normal during the day or two before death

78 **Adiposis Dolorosa in Relation to Syphilis**—Pizarro summarizes the history and literature of Dercum's disease, and describes a case from his practice which seems to throw light on its etiology and treatment His patient was a woman of 52 who had menstruated early and borne a child young The child died in two hours, and there has been no pregnancy since except one possible early abortion At 46 the first sign of the adiposis dolorosa developed, and menstruation ceased at 48 At the age of 52 the disease in the mixed form of adiposis, was extreme, as also the pains, but the urine was normal On one occasion the repeated Wassermann test elicited a positive response, and on the basis of the single Wassermann reaction vigorous mercurial treatment was applied and improvement was promptly evident The blood findings on repeated examination confirmed the clinical improvement The masses of adipose tissue retrogressed almost entirely The patient had no further spontaneous pains and instead of the huge unwieldy adiposis as shown in the illustrations she is said to have become agile and capable (*agil y dispuesta*) Her weight at any time is not mentioned She had been given ovarian treatment at first and this was kept up with iodid after suspension of the mercurial treatment Pizarro presents his conclusions in the form of twelve questions, asking, Is it possible that adiposis dolorosa is of syphilitic origin? Has treatment as for syphilis been tried before in this disease? If it has been tried, and no benefit resulted, could this have been owing to inadequate dosage or other defective technic? In this case were the adiposis dolorosa and the syphilis independent or not of each other? Is it not a common occurrence that syphilis aggravates dystrophies and other manifestations of defective functioning of the ductless glands?

88 Complications of Vaccination Against Typhoid (K voprosu a posliedstviyakh protivotyphoznikh privivok) G A Akhiezer

82 **Vaccination of Children Against Typhoid**—Medovikoff vaccinated seventeen girls from 8 to 14 years old, in order to find out whether antityphoid vaccination produces in children any reaction, and whether agglutinins form and accumulate during the period of vaccination He used Wright s bouillon vaccine, Kolle's agar vaccine or Vincent's vaccine each in about a third of the children Three injections were

made, each hypodermically below the scapula, with eight day intervals The dose for the first injection was 0 5 c c per 60 kg of body weight, for the second injection, twice and for the third three times the amount used for the first injection The local reaction showed the next day in the form of redness swelling and tenderness, in some cases the axillary glands became swollen The general reaction was insignificant merely slight headache, some malaise, and a very slight elevation of the temperature which was somewhat higher after Wright's vaccine Before the first injection it was established that the serum (1 20) dilution did not agglutinate typhoid bacilli After the vaccinations, the agglutinins began to appear by the sixth day after the first injection and kept increasing after the subsequent vaccinations Thus any of these varieties of vaccines can be used as with each and all of them production of agglutinins takes place His experience also shows that in children as well as in adults, immunity against typhoid infection can be successfully induced and thus they can be protected against this disease in case of an epidemic

84 **Neurasthenia in Soldiers on Active Service**—Gerver found from repeated observation of neurasthenia in soldiers that it manifests itself in the war environment with the same clinical symptoms as in time of peace The specific features are impulsive ideas and phobias, even the entire sphere of consciousness may suffer The existing conditions of warfare imprint special features on the neurasthenia The forms with agitation show during periods of hot battling, while trench warfare elicits the more torpid forms of neurasthenia The physical symptoms also are the same as in time of peace headache dizziness tinnitus and diminished hearing Clavus that is, an acute sharply localized pain especially in the occipital region is also very common and hysteria is a frequent complication

85 **Mental Disturbance in Soldiers**—According to Urstein's observation, psychic disorders caused by brain trauma develop usually only when more or less extensive portions of the gray matter of the cortex are involved, though it is possible for even circumscribed lesions of the brain as, for instance, fracture of the skull, hemorrhages, etc., to affect the mind The immediate result of brain trauma is mental confusion The patients appear somnolent, dazed forgetful and absentminded In severe cases unconsciousness may last for hours and even days Other symptoms are headache fainting, dizziness, vomiting, slow pulse, pupil disturbances, paralysis and convulsions The mental confusion usually shows immediately after brain trauma, but in some cases only after an interval of hours or days In addition there are observed changes in the character, excessive sensitiveness excitability and irritability, exhilaration, maniacal states and hypochondriac ideas In general, the clinical picture resembles that of traumatic delirium The symptoms of delirium become more pronounced when the course is unfavorable, which may be due to abscess formation or to a meningo-encephalitis In such cases somnolence sets in, followed by coma, convulsions, paralysis and rise in temperature

The most frequently observed psychosis was catatonia, next in frequency psychopathic constitutional anomalies, epileptic insanity and finally manic-depressive states Urstein has also encountered cases of the so-called exhaustion psychoses, hysterical psychoses and progressive paralysis of the insane The latter was observed only in soldiers over 30 years old There does not seem to be any specific psychoses, according to Urstein He claims that a psychosis develops only when there was a certain predisposition That is the elements of the psychosis were present before the man went to war, the latter but hastened its development In general the so-called war psychoses do not differ from those in time of peace though the clinical symptoms may be somewhat peculiar depending on the character of the warfare.

86 **Aneurysm of Pulmonary Artery**—In 271 cases of so called internal aneurysms, Nikolaieff found aortic aneurysm in 86.3 per cent of the cases, while the pulmonary artery was involved in only two cases, that is, in 0.7 per cent He reports in detail a case of aneurysm of the pulmonary artery in which the diagnosis was confirmed by necropsy The main symptoms were dyspnea, repeated and abundant hemoptysis which yielded to rest, and a marked systolic murmur heard at the back, especially in the interscapular space at the base of the lungs The auscultation phenomena at the base of the heart were changeable, sometimes systolic, sometimes diastolic murmurs were heard, and they were very inconstant appearing only during disturbed compensation in the lesser blood circle Necropsy revealed some narrowing of the aortic orifice, and considerable dilatation of the branches of the pulmonary artery The diameter of the left branch was 2 5 cm The right and left ventricle were considerably hypertrophied the cavities not much dilated Another feature of the case was the protracted course—six and a half years—and it might have been longer if the patient had not succumbed to intercurrent pneumonia The Wassermann test was negative, Roentgen examination gave indefinite results

87 **Poisoning from Denatured Alcohol**—Eleonskaia comments on the extreme frequency of poisoning from denatured alcohol in the Petrograd hospitals soon after the sale of liquors was forbidden From 123 to 332 persons per month were treated in one hospital, while in another during the six months 1 292 cases were admitted As denatured alcohol contains about 1 per cent of wood alcohol which affects the vision causing amblyopia, the latter was a very common occurrence in cases of denatured alcohol poisoning Of 1,432 men treated during 1915 for poisoning from denatured alcohol, 6 per cent suffered from amblyopia Half of this number drank denatured alcohol only, while others used in addition cologne water and furniture polish It required three or four months for the onset of visual disorders, and this occurred usually only after large quantities of alcohol had been imbibed The main symptoms were decline in visual acuity, especially of central vision, and disturbances in color sense especially for red and green Occasionally central scotoma for all colors was observed, including white Narrowing of the field of vision was observed in 15 out of 40 cases examined and the fundus was found changed in 61 out of 96 cases (hyperemia of the papilla, blurred outline, pallor of the temporal half of disk, etc) The pupils were usually normal Abstinence from further use of denatured alcohol brought in many cases improvement of vision, but very slowly and imperfectly In general the visual disorders caused by the use of denatured alcohol are milder than those brought on by pure wood alcohol, but they are more severe than those from plain alcohol

95 Localization of Peripheral Facial Paralysis (Bijdrage tot de localisatie van perifere facialis-verlammingen.) J G Drossaers

89 **Spasmophilia in Children**—Stheeman found in examining 100 children that the Chvostek and Erb signs were both positive in 32, the latter alone in 14 and the former alone in 17 Thus in 100 children, selected at random, 46 per cent presented the Erb phenomenon—which is regarded as pathognomonic of spasmophilia—and 63 per cent presented this or the Chvostek. Only 4 of the children had actual tetany The larger proportion reacting, and the more pronounced reactions were in children between 7 and 12 His record

thus testifies to an unsuspected prevalence of a tendency to abnormal spasmophilic nervous conditions in older children Children inclined to asthenia seem most predisposed to it Chronic digestive disturbances and neuropathies also afford a predisposition An unstable vasomotor system, excitability of the abdominal vagus or sympathetic system, and the facialis phenomenon suggest spasmophilia, and electric tests confirm the diagnosis Treatment should be instituted without delay to correct whatever is wrong, with digestive disturbances, keeping the child in bed for a time with individualized dietetic treatment. With nervous loss of appetite or nervous vomiting, a change to another environment is indicated Outdoor life is of paramount importance when the general condition permits, that is, when there is no serious intestinal disturbance In all cases phosphorus-cod liver oil will be found of decided benefit

A number of cases are reported in detail to illustrate the variety of clinical pictures that may be induced by the spasmophilic tendency, from spasmodic stenosis of the bowel, rotatory tic and petit mal, palpitations, gastric achylia, enuresis, hyperchlorhydria and spastic anemia to choreiform movements and the so-called umbilical colic All of these yielded to the treatment outlined above The spasmophilia of the vegetative nervous system, vagotonic spasmophilia, may cause severe and recurring abdominal pains One girl of 10 was long treated for tuberculous peritonitis on account of a tumor palpated in the abdomen The spastic constipation and Erb reaction, with the favorable action of belladonna and castor oil, finally cleared up the diagnosis as spasmophilic vagotony, and a complete cure followed systematic phosphorus treatment Another typical instance is that of a boy of 10 with recurring attacks of vomiting, with fever, and severe pain at times, beginning to the left of the epigastrium and spreading through it, lasting for an hour or two The sympathetic plexus was tender and the pillow was wet with saliva at night Under phosphorus-cod liver oil and belladonna the pains subsided and have never returned, and the bowel function is regular By the end of two weeks the previously lively Erb reaction had also vanished and the child seemed bright and well

93 The Birth and Death Rate in the Netherlands—Methorst gives a number of charts comparing the birth and death rates in the Netherlands with that in other countries through the five-year periods since 1840 Other charts and maps show the death rate by months, the various causes of infant mortality by districts, etc In the Netherlands before 1898 the infant mortality in the cities was higher than in the small towns, but since then the proportions have been reversed In 1911, the cities with over 100,000 inhabitants had an infant mortality of 9 88 per 100 born living, and by 1914 this had been reduced to 6 88 In the towns with less than 5,000 inhabitants the figures were respectively 15 81 and 10 60 The statistics cited from twenty-five countries place the Netherlands eighteenth on the list of high infant mortality, Russia heading the list with 25 8 mortality among 100 infants born living, Hungary and Spain, 18 4, Prussia and Japan, 15 9, Italy and Belgium, 14 1, France, 12 6, England, 11 7, Switzerland, 11 5, Netherlands, 11 4, Australia, 7 8, Norway and New Zealand, 7 The Netherlands stands twentieth in the figures for the general mortality In the Roman Catholic families of the Netherlands 287 births are credited to each 1,000 married women under 50, in the Protestant families 219, in the Jewish, 157, and in other families 88 These figures are for 1909-1910 The infant mortality classified in this same way for about the same period shows that of 100 children born living in Roman Catholic families, 13 6 died within the first year, in the Protestant families, 9 5, and in the Jewish, 7 5 The general birth rate per 1,000 nts was in 1840 about 34, and had dropped to 28 in Netherlands thus stands fourteenth on the list of -five countries cited with high birth rate

98 *Congenital Talipes Valgus (Om medfødt Pes valgus og calcaneo valgus) H C Slomann

99 The Extracardial Circulation (Nyere Undersøgelser over Arteriernes Evne til at kunne befordre Blodstrømmen) H I Bing

98 Congenital Talipes Valgus—Slomann comments on the scanty literature on this type of congenital clubfoot, declaring that congenital flatfoot is one of the most frequent congenital deformities, far more frequent than talipes varus, which the textbooks say is the most common form of clubfoot At the same time the congenital flatfoot is of essential clinical importance It is a deformity which calls for treatment and responds readily to it He gives illustrations of two typical cases and the clinical details of these and three others out of his fifteen cases in infants in the last three years During this period he has encountered 104 young children born with deformities, congenital dislocation of the hip joint in eighteen and only seven new cases of clubfoot The latter was bilateral in all, but most pronounced on one side Only one of the children had been born with breech presentation One of the mothers also had congenital flat foot The deformity may correct itself in a few months from the exercising of the muscles when these alone are responsible for it But when the bony framework of the foot is abnormal, spontaneous correction is out of the question In any event, unless correction is complete before the child starts to walk, the deformity is fastened for life when the weight of the body is borne regularly on the foot An instructive case of the kind is that of a girl of 13 born with left talipes calcaneovalgus which had apparently corrected itself and there seemed to be nothing abnormal about the feet At the age of 12, however, the use of the left foot caused much pain, the findings and disturbances characteristic of tender and painful flatfoot

In treatment of congenital flatfoot, the simplest means to correct the contracture are the best, operative means are unneeded and irrational when it is merely a question of shortening the overstretched muscles They regain their elasticity when given a chance to contract He has always been successful in correcting contracture of this kind by patient and cautious stretching of the muscles under general anesthesia—the muscles involved are small ones and the forepart of the foot affords a firm hold He says that Stern found it necessary to do tenotomy in nine of his twenty three cases, and possibly the deformity was so extreme that the knife may have been indispensable But bloodless stretching should at least be given a trial in every case before resorting to the knife Everything favors beginning the treatment early, so that the correction will be complete before the child starts to walk The use of the foot with talipes varus aids in the correction but with talipes valgus it undoes what has been accomplished, unless correction is absolutely complete The severer the deformity, the earlier treatment should be begun, but it is seldom necessary to begin before the child is 8 or 9 months old During the preceding months daily manipulations of the foot along the lines of correction may accomplish alone the desired result, and will facilitate it in any event General anesthesia is usually necessary for the complete correction Several sittings may be required at eight or ten days intervals, the foot and leg in slight overcorrection in a plaster cast This fixation is kept up for from three to six weeks and then a small leather correcting appliance is worn, removed every day to pert massage of the plantar muscles and of the leg and bathing When this is discarded a flatfoot shoe is worn, and at night the overcorrecting bandage This not only holds the skeleton in the corrected position but relaxes the weak and stretches the overstrong muscles Any tendency to permanent overcorrection is soon overcome by the use of the foot These measures must be kept up until the naked foot keeps the normal shape unmodified by excessive weight bearing As a rule several years are required for this But only by this means will they be saved from flatfoot distress in later life

VOL LXVI, No 25 CHICAGO, ILLINOIS JUNE 17, 1916

SOME OF THE LARGER PROBLEMS OF THE MEDICAL PROFESSION *

RUPERT BLUE, M D
Surgeon General, U S Public Health Service President of the American Medical Association
WASHINGTON, D C

The profession of medicine enters into and touches every human activity from the first kindling of the vital flame until life's candle flickers out The joys of being and the sorrows of life, the travail of labor and the relaxations of idleness, the opulence of riches and the meagerness of poverty have running through their web and woof the fine blue thread of the calling which has as its ideal the physical salvation of mankind Throughout the nearly seventy years of its existence the American Medical Association has clung with unfaltering fidelity to the doctrine of the prolongation of human life and the relief of the miseries of man In peace and in war, in prosperity and in public calamity, in crowded city and on isolated frontier, despite all opposition, it has moved steadily forward toward the goal of health, recognizing neither creed nor sect, neither school nor system, but solely the sacredness of its objects The catholicity of its principles, the high altruism of its ideals, and the broad basis of its humanity have preserved it inviolate against the attacks of those who would revert to primeval incantations, ignorance and chicanery in the prevention and remediation of disease The passage of the years is marked by a trail of discarded superstitions on the one hand and by the monuments of scientific progress on the other, and the very obstacles which have been thrown into the path which we have trod have proved stepping stones to higher ground

Today, as we look back over the achievements of this Association, we receive inspiration from the work of those who have gone before us The researches of our medical forebears are a priceless heritage, entailed for all future generations But as we review the triumphs of the past and plan fresh victories for the future, our happiness in the joy of this pleasant reunion in the bonds of scientific fellowship is not without its note of sadness

Since our last annual meeting death has called from our midst a number of the strong men of the profession of medicine In the loss of that lovable and kindly gentleman, Dr Edward L Trudeau, the world has been deprived of a great leader in the antituberculosis movement In the death of Surg -Gen George M Sternberg our profession and the nation have lost an officer eminent in science and a pioneer in the field of military hygiene In the passing away of Dr Henry B Favill the country has been robbed of a powerful intellect which was being more and more devoted to the cause of good government, clean politics, municipal improvement and sanitary progress In the untimely death of Dr William L Rodman the Association has been bereaved of its President, and America has lost a distinguished surgeon and a public-spirited citizen We would also remember at this time the members of our profession and Association who, through love of their fellow men, volunteered to serve mankind in those countries unhappily divided by war and stricken by pestilence, and who by so doing sacrificed their lives to the ideals of our profession

By reason of their relation to the Association, we glory especially in the accomplishments of Rodman and Favill, and extend our condolences to their sorrowing relatives and friends, with whom we mourn In the solemnity of this moment let us take inspiration from their lives, that their ideals may pass on to us, and that we may more faithfully discharge our duties to mankind

The limitation of time does not permit the recitation of the scientific accomplishments since our last meeting, neither does it suffice to enumerate the fields of activity which lie fertile before us The movement for race betterment, the increase of child hygiene and the restriction of child labor deserve and receive the approval and assistance of this body The necessity for the advancement of the campaign for mental hygiene, the cure and prevention of tuberculosis and cancer, and the improvement in the collection of vital statistics, particularly morbidity statistics, is so great as to require no argument
